The Alexandria Library supposedly had an extensive catalog compiled by Callimachus in the form of *Pinakes* in 250 B.C. There is, however, some element of doubt whether this was actually a catalog of the Alexandrian Library or merely a bibliography compiled by the celebrated first cataloger. Norris suggested the possibility that Hermippus, an assistant to Callimachus, may have actually compiled the catalog in 220 B.C.^[6] It was described as a classified catalog complete in 120 books, but very few fragments exist.

Witty was able to trace only about five true fragments, which were in reality only quotations from the original. The other conjectured remnants were found to be “oblique references” by ancient authors to the bibliographical work of Callimachus.^[8] The term *Pinakes* (singular: *Panax*) was first used by the Greeks to indicate the tablets placed above the library press that served as a guide to its content and later denoted a catalog.^[8] The actual title was “Tables of those who were outstanding in every phase of culture and their writings—in 120 books.”^[8] The fragments reveal a newsy biobibliography of the works of the period with information more applicable for a biographical work than a catalog. Bibliographical information was comprised of a stoichiometric note (number of lines in text) and probably the first words of a work. The entries were subdivided by author or by chronological order.

The primal catalogs through the height of Greek civilization can be conjectured as quasiclassified with a broad subject and form arrangement that resembled an embryonic shelf list. The title concept was not firmly established so that opening words of text were of great importance and were always employed. The author was frequently cited without further reference, a practice that did not cause confusion in view of the paucity of works. As a result one of the most unique contributions of the Greeks may have been the first use of the author concept, for the traditional practice of the Orient has been under title.^[9] The Tripitaka, the source of Buddhist scriptures, was organized only by title.

The Roman period was marked by scanty information regarding catalogs and cataloging. Public and private libraries were common during this period, depending largely upon the works of the Greeks, which were the foundation of Roman culture. Rolls were generally separated by Latin and Greek with general subject divisions used within both categories, and probably an attempt was made to retain all the works of a single author together under the relevant subjects. Two varieties of catalogs, the classified and the bibliographical lists, were prevalent with the former based on shelf arrangement and the latter seeking continuity through authors. Both ordinarily included

titles and/or first lines, number of lines in work, and frequently appended biographical information. It was clear that the Romans continued the precedence as established by Callimachus adding nothing new to the art.^[7] The beginnings of Christianity brought little change to the Roman conceptions of the library for the first seven centuries, except the addition of new works, and works of the church fathers supplementing or even supplanting the authors and philosophers of Greece and Rome.^[10] Gradually, however, public or temple libraries began to decline, especially after the third century when Christianity became the state religion. In A.D. 336 with Constantinople now the center of the Roman empire, the libraries of Rome were rivaled by the collections assembled by a succession of emperors who as a whole supported libraries and scholarship until the conquest by the Turks in 1453. The great libraries of the empire slowly were dispersed or suffered the ravages of neglect. Few extant accounts actually depict the dispersal of the manuscripts and the razing of the temple structures.

Middle Ages: Early Period (Fifth Through Eleventh Centuries)

The fall of Rome in the sixth century brought about a decline in scholarship with the deliberate destruction and dispersion of the public or temple libraries as well as many private collections. The next 10 centuries for the libraries of the Western world would be characterized by small collections of surprisingly similar manuscripts in the many monasteries established in this period. The austere life of the monastic orders was not entirely new; the tradition existed among the Essenes during the early days of the Christian period. The place of books in the monastery was important, for monks were admonished to read, meditate, and copy for the glory of the afterlife. One of the outstanding monastic clerics to whom libraries owe a debt was Cassiodorus,^[11] who after serving in public life retired and founded a monastery at Vivarium in Benevento (southern Italy). His respect for learning was clearly reflected in his famous *Institutiones*, which served as a scholarly model for the many orders and furnished an annotated guide to what he considered valuable.

These monasteries were the major instruments of education, such as it was, and were the primary vehicles in the preservation and production of books. The need for library catalogs, however, was limited during this early period, with efforts directed only toward an inventory record. One of the most elementary type was a list of books given by Gregory to the church of Saint Clements. It consisted of a marble tablet inscribed with an introduction or prayer and a few treasured Biblical works.^[12] The poetical catalog composed by Alcuin of York in the eighth century was a unique form that was in reality a list of famous authors or a bibliography, although it was reputed by some to be a catalog of the York monastery. Another simple listing of

this period was Saint Augustine's *De Trinitate*. This was merely a list of works transcribed on the final flyleaf of a book.^[9] Emperor Louis the Pious (814–840) actuated the compilation of catalogs when he decreed that monasteries and cathedrals should make a list of all the books they possessed.^[13] These early catalogs or inventory lists were thus fashioned by the immediate need for a list of material possessions. The books were generally arranged not by author but by the importance of the work, with precedence given to the Bible and other religious works and with secular works placed last. In addition, these terse lists were not indicative of the full contents of the works included, because it was common practice during this period to bind several works by the same author, or treatises by various authors but on similar subjects, within one cover as an economy measure. Thus a small collection of 10 volumes may actually contain nearly double this number of distinct works. The purpose of the list was to identify the book rather than analyze the contents of the physical volumes. Fortunately, Armarians realized the value of a more complete analysis of at least the distinct works. Several catalogs of the ninth century provided a listing of the works within each volume and the "number of volumes or rolls in which each work was contained."^[9]

One outstanding literary work, *The Myriobiblion*, is indicative of the bibliographic contribution of the period. It was compiled ca. A.D. 842–848 by Photius, patriarch of Constantinople. It bore a strong resemblance to the *Pinakes* of Callimachus and was a primitive but interesting review of approximately 280 works of the period with bibliographic, biographic, and critical information.^[14] The Upper Rhineland monastery at Lorsch in the tenth century produced a more typical catalog in the following order: liturgical works, the Testaments, theological and patristic works, lives of the saints, and last poetry, with a few of the classic authors.^[13] Catalog production between the ninth and eleventh centuries was surprisingly active. Gottlieb listed 24 catalogs from the ninth century, 17 from the tenth, and 30 from the eleventh.^[15]

The period of the early monastic and cathedral library catalogs may be characterized as a period of rudimentary methods. The earliest catalogs were crude lists, frequently inscriptions, without apparent order or sequence, which later became parchment inventories placed near the book presses and further expanded into more distinctive works as the library grew. The manuscripts were arranged, or classified, by broad subjects. The most common order was: archives, scriptural texts and commentaries, constitutions, council and synodal proceedings, homilies and epistles of the fathers, lectionaries, and legends of martyrdom with secular literature frequently placed in a subsection divided by the seven liberal arts: grammar, rhetoric, logic, arithmetic, geometry, music, and astronomy.^[13] This arrangement reflected a utilitarian as well as a philosophical aspect. As long as the collections were small the divisions were simple. Frequently, secondary arrangements

were by order of acquisition or size. The widely varying catalogs of the early Christian period were most nearly like the modern shelf list and provided an inventory designed to facilitate record keeping while showing the location of the work.

Middle Ages: Late Period (Twelfth Through Fourteenth Centuries)

Twelfth century

Catalog arrangement of this century continued in the same casual manner. The extant portion of the 1158 catalog of the monastery at Prüfening indicated a chronological sequence for all books that were grouped after the Biblical works. The compiler was foresighted enough to provide space for the collection of later acquisitions.^[13]

The Christchurch catalog, 1170, was the first to use a system of reference letters placed both within the catalog and the books.^[16] The Lincoln Cathedral Library Catalog of ca. 1200 continued the practice of including opening words as well as the title and added another feature, an introduction.^[6]

Although only a few catalogs have been discussed, the twelfth century was characterized by a large number produced on the continent with Gottlieb listing 62 examples.^[15] The typical catalog, however, remained an inventory list compiled with a general lack of system on a two-column parchment page. The broad subject arrangement was the accepted pattern with titles generally subarranged in chronological order rather than alphabetical by author. Author's names served primarily as a means of identification with little attention given to form and accuracy. The information listed was extremely brief, composed of author's name and short title, frequently with the opening words of the work and occasional statements concerning physical conditions, color, or number of items in the volume. The addition of the beginning words of the text was necessary to aid in distinguishing anonymous works and works with identical or similar titles. As a whole the information included was so vague that it offered little aid outside the context of the individual library.

Thirteenth century

The thirteenth century found a continuation of the shelf or press arrangement with short titles and opening words. The Glastonbury catalog of 1247^[6] employed a unique and remarkable classification. Books that were by obscure authors but yet valuable for subject information were placed under the subject. Those by well-known writers were placed under the author. This system, in effect, was an attempt to select an entry that would best serve the needs of the user. The beginnings of union catalogs can be traced to the *Registrum Librorum Angliae*, 1250–1296,

which was an unfinished attempt to record the holdings of 183 English monastic libraries.

The earliest information regarding the libraries of the universities came to light in the catalog of the Sorbonne at the University of Paris in 1289. It contained over 1017 Latin titles but only four in French, arranged by 10 major divisions: the seven liberal arts (or the trivium and quadrivium) plus theology, medicine, and law. Authors were arranged alphabetically within each division followed by the title and the beginning words of the text.^[7]

Fourteenth century

The fourteenth century provided an abundance of examples although few new innovations. Subject arrangement was common; five of the seven catalogs described by Norris had this arrangement. The catalog of Christchurch, Canterbury, 1313–1331, was considered to be the first to adapt an alphabetical order under at least one subject heading, theology. In addition a system of press marks was present as well as an inept attempt to list the works of each volume.^[6]

The Exeter Cathedral Library catalog of 1327 was an author catalog with only one subject heading. It listed the value of each book, as it was probably intended only for the inventory of church property.

The catalog of the Saint Martin's Priory at Dover of 1389 had an unusual three-part arrangement by location number. The first section was intended for the use of the librarian, consisting of a tabular shelf list; the second was a duplicate of the shelf list with enumeration of the individual works bound within each volume; and third was a crude alphabetical-analytical index designed to indicate the location of an individual treatise in a volume.^[17] The addition of the author index to this inventory list added the dimension of a true catalog, which was not evident in many of the examples up to this time. The catalog of the Leicester Abbey in 1394 exhibited a similar characteristic with a double catalog of authors and subjects.^[13]

The catalog of the Library of Meaux Abbey, 1396, was arranged by the location of the bookshelves, which were scattered about the abbey. It did have a more distinct feature, however, in its introductory remarks concerning the origins of the catalog; these were later to become an interesting addition to book catalogs as late as the nineteenth century.

The catalogs of the fourteenth century were the familiar inventory lists arranged by broad subjects with books assigned to a designated or fixed location on the shelves. In effect this was merely the classification of shelf space within the presses, which were marked as to content. This concept encouraged the use of press marks, which could readily be added to the books as an aid in reshelving. Each individual library devised a unique mark generally relying upon alphabetic characters and upon Roman and Arabic numbers. The Dover (1389) and Durham (1391) catalogs

established the practice of recording the “opening words of the second leaf of each book,” which was to become an almost universal method in the next few centuries.^[16]

Modern Period

The fifteenth and sixteenth centuries were a period of sweeping sociological, economic, and cultural changes that reverberated throughout the whole social structure. The Reformation shifted the power from the old universal church to a wider range of authorities with secular organizations assuming more responsibility in many of the nations. In England, the decline of the monastic orders tended to shift the collections of books to the private, college, and university libraries, which was impelled by the suppression of the monasteries during the reign of Henry VIII, 1536–1539. The collegiate libraries were to suffer some of the same harassment in 1549 from the Commissioners of Edward VI, who sought to root out “superstitious literature.” In spite of these difficulties the influence of the Renaissance on scholars, who were nurtured within the academic community, caused them to emphasize the collection and preservation of books as the mark of gentlemen and valuable assets for a nation. The beginning and rapid development of printing from movable type assured a wide distribution of multiple identical copies of a work, a technological advance hitherto unknown to the world. The expensive manuscript books with parchment pages, beautiful and unique, ceased to be the primary form of communication. Printed books were the beginning of a revolution with which bibliographic organization had to keep pace. No longer would the written word be controlled by a central authority that closely guarded the use and distribution of ideas. The existing few and soon numerous libraries, though still in monasteries, cathedrals, universities, and private palaces, began to acquire universality. The stagnation of the preceding centuries ended. The private libraries of the past had represented a broad range of tastes, but were limited in number due to the cost and paucity of the manuscript codices. The church had reluctantly retained the works of the ancients, primarily as a method of education rather than for their contribution to Christian ethics. The university libraries and expanding private libraries began to seek a wide representation of works and assumed the role of conveyors of human knowledge rather than the preserver of a few standard works. Leaders such as Naude and Dury recognized the value in retaining all types of works as the tools of the scholars and the links to the past. The printers and booksellers, albeit with large economic motivation, provided the substance of libraries as well as forging a major link in the bibliographic chain through the efforts of such giants as Maunsell. As the libraries developed, the methods of bibliographic organization slowly evolved despite poor communication, a lack of clear objectives and functions, minimal economic resources, traditionalism,

and the relegation of library usage to a selected few. By the end of the sixteenth century the dawn of the new era was at hand and blossomed fully in the next three centuries.

Fifteenth century

The beginning of the century brought the *Catalogus Scriptorum Ecclesiae* by John Boston, a monk at Bury Saint Edmunds. Apparently he intended to continue the *Registrum* of the previous century, as identical code numbers were employed in both.^[18] He increased the list of authors' names from 85 to 700 and included additional libraries as well as biographical information.^[17]

The catalog of the private library of Amplonius Ratinek de Berka, 1410–1412, which was later given to the University of Erfurt, represented one of the more carefully classified catalogs of the period. Arrangement was by broad subjects such as grammar, poetry, logic, rhetoric, mathematics, natural philosophy, metaphysics, moral philosophy, medicine, law, and theology, with the contents of each volume fully listed and frequently extending to 10 or more items.^[19]

The collegiate catalog of Peterhouse Library, Cambridge, 1418, was arranged by the traditional subjects and indicated two distinct collections, one for reference, which consisted of chained books, and one for lending to the “fellows.” Its unique feature lay in the use of the last word of the second folio in addition to the widely accepted practice of indicating the first words. This pattern was also followed by the Cambridge University Library catalog of 1424.^[6]

The Vatican Library catalog of 1481 depicted the accepted practice of placing the books in bookcases by broad subject arrangement. The catalog was simply an inventory device to show the locations of the materials within the bookcases of the Latin, the Greek, and the Inner libraries, and the Bibliotheca Pontificia.^[10]

The most outstanding catalog of this century was that of the Saint Augustine's Library of Canterbury, 1497. It was comprised of three parts: first, a location list indicating in tabular form the exact place where the books were located and/or the name of the borrower; second, an unfinished alphabetical listing of all books in the library with a reference to the page number of the catalog where the full entries and the press marks could be found; and third, the main section of the catalog.^[6] The latter was a model of uniformity with the general title or that of the first treatise, the name of the donor, the contents (titles) of other works in the volume, the traditional first words of the second work, and the press mark.^[17]

The alphabetical approach with its problem of inter-filing was more common on the Continent than in England during this period. Several catalogs that originated in Austria and Germany revealed the efforts to achieve more logical points of access to the shelf arrangement. An alphabetical catchword index to the shelf list was formulated at

an Austrian monastery at Aggsback; a list of authors, subject designations, and catch title anonymous works were employed as special indexes to the catalog at Melk Monastery in 1483; and dictionary-type catalogs with a multiple-entry approach through author and title catchword were reported at the monasteries of Rebendorf at Eichstaett and Aegidian at Nürnburg.^[20]

The most obvious change during the fifteenth century was a break in the traditional bibliographic organization both within and outside the libraries. Generally, the university catalogs were not as well developed as those of the monasteries. The subject arrangement of the inventory was still the dominant order, but the finding list concept was slowly evolving through the addition of author indexes. Extent of description remained fairly constant with bibliographic comments at a minimum, but exceptions were evident in the Durham Catalog of 1416 which had such information as value, size, doubtful authorship, stolen books, and location.^[6] Thompson reported that the earliest entry of the pages in a work appeared in 1465.^[13] Press marks were used to some extent as in the fourteenth century while the use of the last word as well as the first of each treatise was an innovation. The Saint Augustine Catalog was perhaps the most outstanding product, with its analysis of the parts of volumes through the use of rather advanced cross references, which were given the status of entries.^[18]

Before leaving this century some attention should be given to an important approach devised by Johann Tritheim, who began his bibliographic career with the reorganizing and cataloging of the German monastic library at Sponheim. While engaged in this undertaking, he apparently realized the value of a bibliography of ecclesiastical writers, which he completed in 1494. The *Liber de scriptoribus ecclesiasticis* enumerated 277 works, recorded about 7000 books, and reflected a considerable amount of investigation.^[19] The inclusion of an alphabetical index of authors, arranged by their Christian names, was appended to facilitate the use of the chronological arrangement and established a principle that was to continue as a bibliographical method for many centuries to come.^[19] Thus recognition of multiple access to books was clearly emerging as standard bibliographic procedure with the finding list theory becoming a recognized element within the catalog.

Sixteenth century

The sixteenth century found a continuation of the concept of the inventory device. Some catalogs, such as Saint Martin's Priory of Dover, had gone beyond this by developing shelf lists and analytics. The value of analyzing each part of the physical volume was evident in many catalogs but was by no means universally accepted.

The entry had little resemblance to that of the modern catalog with only title and first words and perhaps last

words of each work. This, however, was to be modified somewhat during this century and substantially during the next as the printed book became relatively commonplace. Catalog production shifted from monasteries to collegiate and private collectors. The century was truly productive with some of the most positive influences for the catalog attributed to Gesner, Trifflerus, and Maunsell. Their efforts stimulated a systematic approach rather than the individualistic methods of the past.

Only two monastic catalogs are of particular value during this century. First, the Syon catalog of 1526 was important because it was the first English catalog to incorporate the idea of Tritheim by including an alphabetical index of authors. It utilized a subject arrangement within the main section with letters of the alphabet denoting subjects. These were then combined with Arabic numbers, which represented accession numbers, to form a complete press mark. Donors and opening words of the second work in the volume are recorded as well as the traditional abbreviated entry. The second was the 1558 catalog of the library of the Bretton Monastery, which was the first to include in the entry the names of editors and translators.

One of the greatest contributions of this century, however, was made by Konrad Gesner, who in 1545 issued the first volume of a comprehensive international bibliographical dictionary entitled *Bibliotheca Universalis*. The work was divided into several distinct parts. First, the main section was comprised of a listing of all the Latin, Greek, and Hebrew authors that were known to the compiler. The arrangement was by the author's Christian name with an added "summary list" of author's names in inverted order.^[19] The second volume was the *Pandectarum*, in which the works of the first volume were rearranged under 21 subject headings that were more extensive than ordinarily found in a typical library catalog up to this point; this represented a marked improvement. The scheme, however, gives the "...impression that it was drawn up empirically and then forced into a pseudo-logical system."^[19] The use of copious subdivisions and an alphabetical index of headings were features that were truly remarkable. As an added bit of information for the book collector, Gesner provided instructions for arranging books in a library. He suggested that books be divided by size and then by some order on the shelves. A catalog of books in shelf order and an alphabetical author index were considered sufficient, although a record by accession number with acquisition and value was also contributory. In addition to these suggestions he pointed out that his *Bibliotheca* could be readily used as a catalog to any library by the addition of press marks.

Additional support for a logically organized library catalog was expounded in 1560 in a manual published in Augsburg by Florian Trefflerus, a Benedictine monk. He stressed the value of a catalog and suggested that five catalogs were desirable: first, one arranged alphabetically by the name of the author; second, one arranged in classed

order or shelf list order; third, one serving as a subject index to the various contents of all books; fourth, an alphabetical index to the third; and fifth, one intended to list books held in reserve because of age or condition. He suggested a shelf mark comprised of a letter designation for size, color, and subject. The first two were represented by abbreviations, but the subject scheme was delineated by the first 17 letters of the alphabet.^[6]

The last provocative work of this century was done by Andrew Maunsell, a London bookseller who in 1595 compiled a bibliography of books published in English. He adopted new methods and shunned the examples of “the learned men that have written Latine Catalogues.”^[21] A dictionary arrangement was followed with a single alphabet of authors, limited added entries such as translators, and subject words. Individual entries were arranged alphabetically by author’s surname rather than the Christian name, and the anonymous works were entered under title, subject, or sometimes both if it would facilitate location. When subject was used it was as a “see” reference to the main entry. This practice was continued in library catalogs and encouraged the custom of distinguishing the main entry. All Bibles or books of the Bible were listed together under the designation Bible to facilitate their location and no doubt influenced later use of uniform headings. The form of entry had a completeness of description lacking in most earlier library catalogs. It was composed of author’s names, translator if present, sufficient name of printer or bookseller, imprint date, and type of format.

It is readily seen that this century witnessed great strides in bibliographical organization, with two of the most important contributions emanating from outside the library itself. The two library catalogs described were significant since they incorporated some of the concepts that were later suggested by Trefferus, Gesner, and Maunsell. Gesner and Trefferus clearly championed the need for several points of access through multiple indexes. Maunsell’s direct and simple approach to the problems of entry word, arrangement, anonymous works, and completeness of description would have a decided influence upon the codes of the succeeding centuries. As the century closed it was clear that a recognition of the need for uniformity and a systematic approach to catalogs and cataloging would soon be a reality rather than just the vague promise of a few erudite bibliographers.

AGE OF THE FINDING LIST

Modern Period

Seventeenth century

The dawn of the seventeenth century found a continued lack of understanding regarding the nature and purpose of library cataloging. The familiar concepts persisted with

shelf arrangement designed for administrative reasons rather than the needs of the patrons. The classification by size as well as subject gained in popularity. The finding list idea, however, was clearly established with author indexes widely advocated. The development of the printed catalog was a highlight of this century. The old manuscript catalog had been laboriously produced while the new lists lent themselves to extensive production if the need should arise.

The number of libraries continued to increase, but cataloging methods changed only slightly although there seemed to be some standardization during the first quarter of the century.^[23] The gulf between the medieval and the modern methods of cataloging could be discerned in the precocious instructions given by Naude, Dury, Baillet, and the Bodleian Catalogue of 1674. The first general library catalog that served primarily as a finding list was the Bodleian Catalogue of 1620. The combined efforts of Thomas James and Sir Thomas Bodley produced a catalog that was arranged by the author’s surnames and catchword titles for anonymous works. The functions of the catalog had finally come to the forefront, although it was in an unintentional manner. Bibliographers would continue to extend the points of access that would be valuable to students and scholars. The major philosophical issues involved in catalog construction were in the offing and only in the nineteenth century were they explored more fully.

The Bodleian catalogs were one of the dominant influences of the seventeenth century and would continue to affect all succeeding study of cataloging procedures. The principal figure behind the reorganization of the Oxford University Library was Sir Thomas Bodley, a retired English diplomat, who dominated the cataloging efforts of Thomas James, the first librarian. The initial printed catalog of 1605 was primarily a shelf list of printed books and manuscripts. The arrangement was typical of the sixteenth century, with groupings by the four academic disciplines of theology, medicine, law, and art. Size separated the books further with the folios chained to the reading desks and the quartos and octavos shelved in special locked cases. Individual entries were listed under subjects, alphabetically by the author when known. Anonymous and pseudonymous works were placed under the most significant word of the title or else under the first word. The entry was somewhat more complete, with author’s name in natural order, title, place, date, size, and location, but lacking edition. To the main catalog was appended an alphabetical index of authors and lists of commentators. The original intent was to print the contents of a single shelf on one page, which would allow extra pages to be used as shelf guides. Recent additions were to be included within an appendix.^[6]

In 1613 an alphabetical author catalog was compiled in manuscript form. It was never printed but rather formed the draft for the second catalog.

The 1620 catalog was a milestone in catalog arrangement, as it used a single sequence of authors' surnames (Christian name first), with anonymous works placed under the first or most striking word of the title. This in effect was our modern dictionary catalog in its embryonic stages without the benefit of uniform subject headings. The idea here, as in other earlier catalogs, was to provide a single entry for each book with the author considered the most logical approach. The anonymous works had created serious problems in other catalogs. Entries for them frequently were made under title, under form heading, or under the most striking word of the title. This catalog utilized the latter method, not in the sense of a systematic coverage of subject information but rather as an attempt to establish some assemblage of materials lacking authors by subject words or forms that might be remembered by the catalog user. The titles of the ancient works had never been a unique form of identification and even at this time were considered of doubtful value in their natural order. The catchword seemed to be the logical way to supplement the author list by serving to group materials of a like nature (form or subject) rather than to scatter them by title. Other practices were separation of author's name from title, books by several authors entered under each name, cross references used, and initial or pseudonym constituted an anonymous work.

The last Bodleian catalog of the century was issued in 1674 under the direction of Thomas Hyde; it kept the alphabetical sequence of authors with catch titles for anonymous works as well as making provisions for the assembling of literary units. The preface contained a number of rules that were the most innovative cataloging procedures formulated until the middle of the nineteenth century. Many of the rules had been previously followed in the earlier Bodleian catalogs, but now the rules for main entry clearly supported three continuing concepts. First, the literary unit principle was expressed by the fact that only one form of the author's name was selected for use in the catalog. Second, an assumed name with cross references was used if the author's name was not given. Translations were entered under original author. Finally, anonymous works were entered in one of four ways: 1) under selected form headings for widely used works, 2) under place or edition for less used works, 3) under biography referred to for biography, and 4) under the most striking or subject word of title.^[6] The recognition and assemblage of authors known by different names, under a single form, constituted the first principle of modern cataloging.^[22]

The catalog of the Lumley collection, compiled by Anthony Alcock in 1609, was a typical private library compilation. It was comprised basically of a classed catalog of 2500 printed books and 400 manuscripts that were arranged within eight classes ranging from theology to music, to which was appended an alphabetical index of authors.^[23]

The catalog of the Sion College Library, 1650, was one of the early dictionary catalogs with names of authors and

subjects filed in a single alphabet. Subject headings and authors' surnames were printed in italics, while guide letters were placed at the top of each column of a two-column page with press marks indicating press, shelf, and order of books on the shelf. The general practice of a single entry per book prevailed, with entry either under author or under subject for anonymous works, as used in the Bodleian Catalogue of 1620.^[6]

In addition to the catalogs cited, the status of cataloging was depicted through the contribution of five authors of the period. Gabriel Naude included valuable hints to the librarian regarding the catalog in his *Instructions*. . .^[24] He commented on the desirability of the catalog and suggested the compilation of two: the first, arranged according to classes (morals, sciences, and devotion) and the faculties (theology, physics, law, mathematics, humanities, etc.) with subdivisions; and the second, an alphabetical author catalog.^[24] He pointed out the need for a miscellaneous class, criticized the single access of some catalogs, and exalted the superiority of the systematic arrangement over the fixed location.

John Dury, a protestant clergyman and later Royal Librarian, in 1650 published in England a small pamphlet devoted to library economy. He contended that "the proper charge then of the Honorarie Librarie Keeper in an Universitie should bee thought upon, and the end of the Imploiment in my conception, is to keep the publick stock of learning which is in Books and Manuscripts, to increas it, and to propose it to others in the waie which may bee most useful unto all. . ."^[25] A catalog was the first step. It should be divided by sciences (subject or classes) and languages. He concluded that space on the shelves and in the printed catalog should allow for the "increase of number" and that a reference to the location of the book on the shelves be included. He spoke of the printed catalog as though it were commonplace and called for an annual supplement compiled for use in the library and "made common to those that are abroad," through printing every 3 years. He suggested other methods such as acquisition by exchange, faculty opinions in selection and cataloging, and the selective cataloging of doubtful publications through the use of an alphabetical author catalog with notes regarding subject. Treflerus in 1560 had suggested a similar list but limited it to books that had been superseded or that were worn.

Adrien Barillet, a French librarian and teacher, achieved two distinctions in the field of cataloging: first, the compilation of a catalog in 1682 of the library of Chretien-Francois de Lamoignon with an alphabetical subject index; and second, the formulation of a set of rules for the multientry, alphabetical catalog (subjects and titles for anonymous works). He advocated the use of major subject categories for shelf arrangement that could be further subdivided by chronological, geographic, or more minute subjects; upheld extensive use of cross references; lamented the traditional single-dimensional approach of

the present shelf arrangements as being too restrictive; championed the subject index as the key to the collection through a multidimensional approach; supported the need for an alphabetical index of authors' surnames; and differentiated between the entry of biographical works under specific name or subject.^[20] In general, his remarks exhibited a firm grasp of the value of the catalog for the location of all materials of the library.

Near the end of the century another provocative publication appeared on the construction of the library catalog. The author was a Danish book collector by the name of Frederic de Rostgaard. His somewhat complicated arrangement of a double page, divided into columns, which designated size and the chronological arrangement of entries within each column with accession number and a letter to designate the subject, provided a varying approach to the grouping of books. He also included instructions for an alphabetical index of subjects and authors arranged by surname with reference to size, accession number, and subject.

The seventeenth century was one of growth, experimentation, and expression. The catalog had progressed to the finding-list stage, but still was beset by an absence of universally accepted principles although the many manuals indicated a more systematic attempt. Cross references were now accepted practice and analytical entries were used, especially in the alphabetical subject catalogs as suggested by Baillet. The imprint was now a standard item of the catalog entry, although still limited to place and date. That the subject arrangement was becoming much more refined was due in part to the publication of Bacon's system of classification of human knowledge. The classification that had been used for centuries in the catalogs seemed necessitated by the shelf arrangement rather than by a proven need for a classified catalog forming a systematic arrangement of subjects to provide access to collections. Classification continued to play a more important role as knowledge became more systematized. The value of the subject and author indexes as a means of expanding the approach to the single-dimension shelf arrangement was recognized and discussed by the theorists of the period, but they continued to remain as adjuncts rather than an essential part of the catalog. The use of catchword titles for anonymous works added a limited subject dimension to the catalog, which would progress beyond its original intent. The use of the surname had largely replaced the archaic practice of entry by Christian name, although some vestige of the former remained with the Christian name frequently recorded before the surname. The question of arrangement was still in doubt, with a full range of possibilities. For example, the catalog of the Norwich City Library of 1658–1883 illustrated the shifting trends in concepts of arrangement. The initial catalog followed the subject method but shifted to the author approach in the eighteenth century, then adopted the division by language and size, and finally returned again to the author catalog in

the nineteenth century.^[6] In addition to the question of arrangement, the use of the original language of the book for title, the treatment and analysis of composite works, indication of size, inclusion of eminent printer with date and place, designation of first edition or best edition, assemblage of different editions of every author together in chronological order, and designation of the value of the book were all problems that confronted the cataloger of the century according to Humphrey Wanley, an assistant librarian at the Bodleian.^[6] Many problems would be answered only to be replaced by more perplexing ones brought on by an expanding society; however, the question of arrangement would persist to the present day. The cataloging process slowly developed from the evolutionary examples and rudimentary codes of this century to the more theoretical and logical efforts of the eighteenth and nineteenth centuries.

Eighteenth century

The eighteenth century was a time of stabilization rather than one of innovation. The expanding university and private collections, augmented by a few municipal libraries, grew in size but only slightly in organizational methods. The French code of 1791, which was the first national code, represented the only major contribution of the century toward a solidification of cataloging procedures. The arrangement of the catalog was still dominantly by subject or by size, with the author approach gaining since the publication of the Bodleian of 1620. The spread of new ideas was slow as each individual library approached the preparation of a catalog greatly restricted by local conditions and attitudes. The printed catalog that became so abundant after the seventeenth century did allow for a distribution of examples highly susceptible to the apprenticeship status of the early bibliographers, who were ordinarily not too concerned with theory.

The inventory or shelf list approach had slowly yielded to a more erudite product, the catalog, although the persistent concern for books on the shelves, not the indexing of knowledge, inhibited the process. Some of the methods of classification developed beyond the simple arrangements of the past and expanded the major classes and subdivisions. The Philadelphia Library Company of 1789 exploited the suggestion of Naude, Baillet, and Dury by classifying under three major divisions and 31 classes, which were then subdivided by size. The purely artificial arrangement by size was frequently used during the seventeenth and eighteenth centuries in accord with the suggestions of Gesner and Rostgaard, and perpetuated the major concern for shelf arrangement. Size is still utilized today as a secondary shelf arrangement, although the storage libraries have recognized its value as well as the accession number approach.

The increased information included in the entry was evident in the catalog of the Friends' Library of 1708,

which added place of birth and residence, time and place of death, edition information, and number of sheets in work. Although it was primarily an alphabetical catalog arranged by authors' surnames, a few subject and form divisions as well as titles for anonymous work were included.^[6]

The fourth Bodleian Catalogue of 1738 continued the tradition of the alphabetical arrangement by author and catch title for anonymous titles subarranged in chronological order. The addition of the name of the printer indicated that one of the problems suggested by Wanley had been solved.

The catalog of the Sion College Library departed from its former alphabetical arrangement of 1650 and was reissued in classified order in 1724.^[6] The artificial scheme was similar to many of the period, which was simply a designation of letters to represent not necessarily subjects, but rather book presses and their contents.

Compilers frequently contended that a catalog by shelf order was most suitable, as missing items could be readily detected and the donors could more quickly determine which presses needed books.^[6] The latter reason was legitimate at that time and was reflected in the later library laws of Great Britain and in such American catalogs as that of Harvard, 1723.

The Chetham catalog of 1791 attempted to utilize a "judicious and scientific" arrangement under the divisions of theology, law, history, sciences and arts, and humanistic literature, which could in turn be subdivided as necessary. The lack of an index badly hampered its use until 1826, when some relief was afforded through the addition of an author index, which gave the title of anonymous works.^[6]

Harvard College had the distinction of issuing the first printed library catalog in America in 1723. Its expressed purpose was not for the improved use of library facilities, but rather as a solicitation device to be circulated "to friends abroad." The catalog served as an inventory and was arranged by size with subdivision by author and catchword titles for anonymous works, although the later editions were in alphabetical order.

Twenty years later, in 1743, Yale produced an excellent catalog composed of three parts: a manuscript shelf list, an alphabetical list of authors, and a classified guide or index for student reading that was divided by approximately 23 major classes with appropriate subdivisions. Books were listed under as many as five subjects in order to bring out the various contents of the volume.^[26]

Generally, the catalogs produced in America during the eighteenth century favored the size or author arrangement or a combination of both, with only three out of approximately 24 relying upon the subject approach. Of these, only the Philadelphia Library Company Catalogue of 1789, with its three divisions and 31 classes that were subarranged by size, and the Harvard catalog of 1790, with its 64 classes that chose subarrangement by author, are of particular significance. The use of the index was

slowly evolving as a valuable asset and was frequently found in the American catalogs. The catalogs of the Philadelphia Association Library Company of 1765 and the Library Company of Philadelphia, 1770, frequently made entries under the first or substantive word of the title in addition to the author,^[26] which would later develop into accepted practice. The information contained in the entry was approximately the same as the British successors. In spite of the unique innovations that have been described, the early American catalogs as a whole could be characterized as rudimentary devices primarily serving as an inventory or index, arranged in a single sequence with generally only a single entry for each work.

Near the end of the century the French revolutionary government confiscated a large number of books and manuscripts from a countless number of institutional and private libraries. The code of 1791 was formulated to provide simple but comprehensive rules for organization, beginning with the assembling and numbering of the books and continuing through the mailing of the completed cards to Paris. Playing cards or slips of paper were suggested as a format, which was the first mention of such an approach in any code. The completed code was to contain an accession number, title exactly as recorded in the book unless extremely long, imprint (place, printer, date), size, and other exceptional features. The author's name, as it appeared on the title page or elsewhere in the work, or a word that was most indicative of the subject if anonymous, was underlined for emphasis. Cards were then arranged alphabetically and fastened together by a thread through the lower left-hand corner. The name of the parish or district was recorded at the bottom of the card. A copy was then made on ordinary paper for retention within the district, and the cards were forwarded to Paris. It was reported in 1794 that approximately one million cards had been compiled as a record for roughly three million volumes.^[27]

The close of the century witnessed few new innovations in cataloging procedures. Author, size, and subject or a combination of any two dominated the arrangements with preference to author and size. A chronological subarrangement rather than alphabetical by title was frequently used in the author catalogs, although the size of the collection dictated the practice in this regard. Completeness of description varied, with the catalog of the Friends' Library being the first to use the number of sheets. Analytical entries continued to gain in popularity, as shown in the Yale catalog of 1743 and in the catalogs of the two society libraries of Philadelphia in 1765 and 1770. The inverted form of the author's name was now a reality, in spite of the use of the possessive form by some of the less progressive libraries.

Nineteenth century

At the beginning of the nineteenth century some vestige of the old inventory concept still persisted. Generally, the

catalog was considered a finding list but occasionally was further refined to include the newest Bodleian concept of assembling literary units together. The purpose of the catalog had evolved through two distinct phases: first, the inventory or content of shelves, which was prevalent in the monastic period; second, the finding list, which began with the author indexes and attained recognition with the alphabetical catalog of the Bodleian in 1620. In addition, Akers^[22] acknowledged a third state, that of assembling literary units, which was originally expressed and practiced in the Bodleian Catalogue of 1674. Akers further contended that the stage demanded a highly developed instrumentation with differentiation between author, subject, and title entries, with main entry determined by authorship, and with the finding list function assigned to secondary entries in the event that the main entries were inadequate for quick location of the book.^[22] The catchword title continued to be used throughout this century, but was dominated by Edwards's statement that "of necessity such catalogues must deal rather with the phraseology of title pages than with the subject of book."^[28] As a result of strict adherence to this and the idea of only one entry per book, the development of subject headings was retarded. Cutter very philosophically avowed that after the introduction of the title entries for anonymous books,

...the next step was to make the title-entries not merely for anonymous books but for all which had any good word in the title from which to refer, the object being to provide a means by which anyone who had heard of the book could easily find it.^[2]

Apparently catch titles were considered as an adjuvant means of grouping materials on certain subjects together, and were used by at least 19 catalogs in the United States between 1815 and 1854.^[2] It should be pointed out that Cutter, in 1876, codified the practice of entry by author, subject, title, and form and refuted the notion that "a catalogue must of necessity confine itself to titles only of books."^[2]

This was a century of codes, with 15 major works originating in Great Britain, France, and the United States, not to mention the individual rules as expounded in the introductions of countless catalogs. The number of catalogs produced during the first three-fourths of this century numbered over 1000 (including supplements) in the United States alone. This was the age of the printed book catalog, which was to continue until the waning years of the century, largely replaced by the card catalog in the early twentieth century only to be revived later.

Our discussion for this century will be directed mainly toward the American catalog and the codes developed by the British Museum, Jewett, and Cutter.

Considerable attention was devoted during this century and the early years of the twentieth to the relative merits of the alphabetical author, the dictionary, the classified, and

the alphabetical-classified catalogs. The alphabetical author catalog consisted primarily of the surnames of the authors while anonymous titles were entered by one of the Bodleian code suggestions. Only one entry per book was considered necessary, although deviations from this occurred quite early in the Philadelphia Association Library Company catalog. The dictionary catalog evolved from the author catalog and is an alphabetical sequence of duplicate entries for authors, titles, subjects, and forms. Frequently the name is used in a narrow sense to apply only to a single alphabetical sequence, while in the broadest connotation it indicates the mere alphabetical arrangement of several separate files. The main distinction lies in the arrangement of specific subjects that are in alphabetical rather than systematic order.

The classified catalog is limited to subjects that are arranged in a systematic order so that related objects are grouped together or in close proximity. The subject-arranged catalogs discussed up to this point were habitually arranged in an unsystematic order so the value of a subject, author, and title index was readily seen although not always present at the preliminary stages. Just when the true classed catalog developed is open to debate, since the early subject arranged shelf lists were pseudoclassified. The assumption that the classified catalog developed before the alphabetical is misleading, for without the modern classification schemes and indexes of the twentieth-century classified catalog, it would fall far short in achieving the usability of the dictionary form.^[29] The early works of Gesner, Naude, Dury, and later Brunet were instrumental in an attempt to systematize the approach to knowledge in the library catalog. The lack of suitable classification schemes retarded the full use of the classified catalog, but the nineteenth century brought some alleviation. For the sake of clarity, the term classed catalog rather than subject arrangement or subject catalog will be used in the discussion of the nineteenth and twentieth centuries. The term subject catalog in its broadest sense does not refer to the arrangement, but rather to the inclusion of subject entries.

The alphabetico-classed catalog, which became popular during the middle of the nineteenth century, was basically a merger of the best points of the dictionary and classed catalogs. Cutter indicated that "...the subjects are grouped in broad classes with numerous alphabetical subdivisions."^[3] This definition was somewhat limited and has been expanded by Shera to include two possible arrangements: first, major divisions in alphabetical order with subdivisions classified in an "appropriate manner," or second, classified order for major divisions with subdivisions in alphabetical sequences.^[30] The catalog of the New York Public Library was strongly influenced by the alphabetico-classed concept, although recent subject headings tend toward greater specificity.

In addition, the combined catalog mentioned by Cutter was composed first of a classified catalog and second of a

dictionary catalog, with author and anonymous-title entries, subject entries, other title entries, and subject references to classed catalog.^[2] This approach would be similar to the combined use of a dictionary catalog and shelf list.

In the early part of the century, the popularity of the alphabetical catalog continued despite the fact that the classified catalog was developing into a sophisticated device with systematic classification schemes and author and/or subject indexes. In 1810 (2nd ed., 1820), Jacques-Charles Brunet published a classified bibliography or *catalogue raisonné* of books for booksellers and private bibliophiles; it consisted of an alphabetical author index with full entry to which was appended a classified abbreviated entry catalog or “*table en forme de catalogue raisonné*.”^[29] The latter was devoid of a separate index, although it did have a brief summary outline that provided a cumbersome but nonetheless systematic access.

The *Catalogue of Printed Books* of the Society of Antiquaries of London, 1816, was reputed to be the first true dictionary catalog; it used the duplicate entry approach within a single alphabet, including catchword or subject word for anonymous works as well as for those the authors of which were known.^[31] This practice, however, was followed to a limited extent in the Philadelphia Association Library Company Catalogue of 1765. Eight years later, Robert Watt issued the *Bibliotheca Britannica*, a two-part bibliography with one alphabetical sequence for authors and a second for subjects. His deviation from the phraseology of the title page as the only source of subject headings was to have a profound effect on indexing methods, ultimately producing a dictionary arrangement.^[29] Panizzi acknowledged the influence of R. Watt’s work on his proposed plan, but pointed out that insufficient information had been given “to the titles of books or to the index.”^[32]

As the purpose of the catalog became more clearly defined, libraries began to reintroduce the classified catalog, which incorporated such refinements as systematic classification schemes devised by Bacon, Horne, Brunet, and others. Indexes were not considered an essential part and were comprised primarily of authors, although the Providence Athenaeum catalog of 1837 included editors and translators.^[2] Thus new means of access were evolving through the index, which served to provide added entries for the book catalog.

At the same time supporters of the alphabetical arrangement sought to improve the subject approach. The Andover Theological Seminary catalog, compiled by O.A. Taylor in 1838, was one of the best alphabetical catalogs of the period and was based on the German practice that provided for two separate alphabetical catalogs arranged by author and by subject. He managed to complete the author section but never finished the systematic index.^[26] Taylor was aided by Charles Jewett, a student, who would later adapt his example at Brown University.

The subject index of 1843 to the author catalog of Brown was to serve as an alphabetical and a pseudoclassed index and was comprised of a single sequence of subjects or catchwords, broad subject entries, and specific entries.^[26] Although Jewett only infrequently deviated from the phraseology of the title page, the departure from the traditional concept of Panizzi and Edwards was significant enough to foster a movement that would in time free the subject index from the restraint of title terminology. “The way was now open for the compilation of a full dictionary catalog.”^[26] Three years later a similar catalog was issued by the Linonian Society of Yale, using a single alphabet with author, title, and subject word.^[2]

Another form of alphabetical catalog, issued in 1844 by the New York Mercantile Company, was comprised of an author catalog with an alphabetically classified index. The index was divided into 69 subjects arranged in alphabetical order, with individuals works listed beneath each heading in a similar arrangement.^[26]

The first half of the nineteenth century was characterized by a variety of combinations of arrangements and indexes. The first major group was comprised of catalogs that were arranged primarily by subject or classified order. The most elementary form was by broad classes or subjects in a shelf list order, with works subarranged by accession and chronologically by imprint date, title, or author. An extension of this was close classification with classes or divisions subdivided into more minute facets by a systematic scheme. Both were considered indexes with single or variant combinations of author, title, or subject as optional features, but their presence became commonplace as librarians recognized the need for a multidimensional approach and stopped arguing about whether the patrons sought material primarily by author or subject. The classified approach was considered more difficult to use, which was true until the development of classification schemes and indexes. The problem of looking in two places, however, always will tend to be somewhat of a disadvantage of this arrangement.

The second broad group of catalogs had a primary arrangement in alphabetical order. They were in many cases indexes to a secondary classified order, but the major emphasis was placed upon the ready accessibility of an alphabetical, rather than a systematic, approach. In other words, both were complementary to one another, with a classified system being rather limited without an alphabetical index and the alphabetical system badly limited because of extreme dependency upon the occurrence of letters. Some of the most common types of arrangements in alphabetical order were: subject list or combinations of subject, author, and title to a classified catalog; subject list with works listed beneath each heading with possible indexes for author and/or title; classes with subdivisions in alphabetical order or classified order; and author list with appended subject list in alphabetical or classed order. Some of the more sophisticated types actually developed

shortly after the turn of the century. It is easily seen that the distinctions are not always too clear. The recognition of the value of each type of arrangement precipitated some rather unusual combinations, which testify to the ingenuity of American bibliographers and librarians. The emergence of the dictionary catalog unquestionably demonstrates the growing influence of the public library in American society. The development of a new form, the card catalog, seemed to parallel the new arrangement during the second half of this century.

In 1853 in an introduction to a classified catalog compiled by Ezra Abbot for the Cambridge High School, the changing concepts of authorship were reflected in the placing of anonymous works under the first word of the title if not an article or preposition, societies under name, periodicals under title, and collections under editor.^[33]

The continuing effort to utilize the key words of the title as a source of information slowly led toward the development of the dictionary catalog. In 1854, Sampson Low issued an *Index to the Titles* for the *British Catalogue of Books Published in 1854*. The former classified index with its 34 classes was now arranged in one alphabetical sequence. This new “concordance of titles,” which supposedly presented the “author’s own definition” of his book, was concerned not with subject information but rather with a more ready location device for the booksellers.^[2] The idea was further developed in 1856 by Crestadoro, a former assistant to Low.

Frederick Poole, in 1854, compiled a dictionary catalog at the Boston Mercantile Library with a single sequence of authors, titles, and subjects. The use of subject words rather than independent subject headings continued the obedience to wording of the titles. The catalog was limited to a single line for each work and was one of the first condensed catalogs produced as an answer to the overwhelming costs of the comprehensive printed form. The lack of cross references was unfortunate, as the related subject words were further obscured just as failure to provide for multiple subjects of composite works further limited the subject value. The catalog continued the tradition as employed in Poole’s *Index to Periodical Literature*, which was first begun at Yale for the libraries of the Linonian and Brothers’ Society in 1848.

After leaving the Smithsonian, Jewett became librarian at the Boston Public Library in 1857 and 1 year later issued a catalog for the Lower Hall; it continued the title entry idea with synonymous words scattered but strengthened it with a wider variety of subject words employing duplicate entries to bring out the various aspects of polytopical books. It also included cross references, which were considered the “greatest improvement of all,” from many subjects to others that were of a similar nature.^[2] The authors’ names were placed first under the headings, thus allowing for easy alphabetical arrangement and greater importance for subject emphasis. Jewett thus “...took the first steps, somewhat wavering steps, it is

true, in a different direction.”^[2] He recognized the informational purpose as well as the need for a specific citation and sought to bring about some distinction between subject and title entries. “The idea was not thoroughly carried out, but it had been conceived.”^[2] The prominence of the subject idea continued to develop in the later Bates Hall Index and its supplements. The dictionary catalog was now an immature but accepted method; however, the idea of specific entry was still in a formative stage though regimented by the title page.

Ezra Abbott entered the catalog scene once again in 1861 by embarking upon an alphabetico-classed card catalog for the Harvard University library, where cards had formed a “private card supplement” since 1833.^[34] This practice was not entirely new, as libraries for years had maintained files of “slips” which were integrated into supplements or new editions of the printed or manuscript catalog and served the staff as a supplementary list. Their use was not an American innovation, as they were employed by Abbe Rozier in 1775 for the compilation of an index of publications of the Paris Academie des Sciences; again in 1791 as described in the French code; then by the Society of Telegraph Engineers in London in 1820; and continuously since 1827 by the Trinity College in Dublin.^[35] The British Museum used an 11- by 4-inch slip, which formed the basis for a sheaf catalog begun in 1841.^[35] The first catalog designed for public use within the United States was reputed to be at the Philadelphia Library Company in 1857.^[36] Bates Hall at Boston Public Library instituted a public Card Catalog in 1871 with two rods across the top of each drawer to hold the cards securely.^[35] The University of Rochester was reported to have used them temporarily as early as 1846.^[2] In addition to the use of cards, the Harvard Catalog was the first time a librarian had undertaken a subject catalog that would include true subject headings for each book that were derived from the content of the book rather than the words of the title.^[26] The subjects would not be scattered by accident of alphabet but rather would be grouped together under a common form. To Abbot, the most logical approach was to compile two separate catalogs or indexes, one for authors and one for subjects. The former would follow the usual pattern and be primarily intended as a finding list for determining the availability of a particular book. The second would be made up of subjects, arranged in alphabetical order, which were subdivided by various aspects in a second alphabetical sequence, thus allowing for some of the advantage of the classified catalog. In addition to entries for books, analytical entries for academy proceedings and periodicals were included. He reasoned that none of the three approaches presently used were feasible: first, the closely classified catalog required a knowledge of a complex classification scheme; second, the broadly classed catalog tended to be too general an approach; and third, the dictionary scattered materials in every part of the catalog.^[26] Abbot’s efforts were to have a

decided effect upon the cataloging procedures, particularly upon the extensive application of cards. His suggested subject arrangement was not widely accepted, although it was in part adopted for the dictionary catalog with its many subdivisions, which became a part of the latter. Cutter commented that Abbot's system was "...best adopted for the thorough investigation of comprehensive subjects"; while the dictionary catalog was for "finding quickly what relates to a person, a place or other specific topic."^[2]

The dictionary and classified catalogs were collocated in 1874 by J. Schwartz at the New York Apprentices Library;^[37] he believed that the "abstract" information or "objects," which must be "viewed in their relations to other objects, or as parts," can best be located by the classified catalog, while "concrete" information or "objects," which "may be viewed as complete" in themselves, can best be located by the dictionary catalog. Thus the information supplied by both was equally valuable but "...both methods cannot be united without doing violence to the principles on which each is based." The ideal catalog could be obtained by the acceptance of "both as co-ordinate parts of one whole." The results were first a classified catalog of all books (imprints omitted) arranged by 24 classes, 216 possible divisions, and about 2000 subdivisions. This was prefixed by a synopsis of the classification scheme to facilitate ready location within each class. The second part was an alphabetical listing: authors and anonymous title entries with individual works subarranged alphabetically by title (complete with imprint); titles that do not clearly indicate subjects or topics "whether stated in title or only implied" followed by a list of all books thereon; class headings used as references to classified; and cross references. The subject headings adapted were frequently in inverted order with the noun or substantive first, then followed by an adjective. The catalog exemplified an attempt to use the best of both, but entailed a considerable effort to compile. The twentieth century would find a similar procedure being used with reference cards placed in the dictionary card catalog that directed the user to the shelf list for general and voluminous classes of information. This approach has never been extensively employed and certainly has great possibility for allowing more selective inclusion in the dictionary catalog while utilizing the ever-present shelf list as a systematic access.

The catalog of the Boston Athenaeum of 1874 was a monumental product of this period and embodied the most advanced thinking of Charles Cutter, who is most clearly identified with the dictionary catalog. The catalog was begun in 1856, the year that Poole assumed the post of librarian, and continued in various stages of development until Cutter became librarian in 1868. Cutter was visibly displeased with the preceding efforts, as he sought to achieve high standards with complete and carefully constructed entries. Author headings were meticulously

established with full names and identity of authors of anonymous works if possible; otherwise they were entered under the first word of the title. Unique subject headings were employed without regard to phraseology of the title, which had become accepted, if not universal, practice by this time. Contents notes were added for each collected work with analytics made for these under author, title, and subject as well as entries for periodical articles and society publications. This was a tremendous feat, but he considered the catalog to be the key to the library collection. At the other end of the spectrum during this same year, Poole published a finding list at the Chicago Public Library that was simply a reproduction of the shelf list with brief bibliographic information. The popularity of such abbreviated lists persisted throughout the remainder of the century. The Boston Athenaeum catalog became the model of the period, with its dictionary arrangement by author, title, and subject with form occasionally denoted by references. The acceptance of the dictionary catalog was then almost universal within the United States, although a few classed catalogs were produced.

In addition to the publication of Cutter's *Rules* in 1876, four other events occurred that were to have an effect upon cataloging. First, the founding of the American Library Association (ALA) united and concentrated efforts in the direction of cataloging with discussion and activities centering around the advantages and disadvantages of the card or book catalog, the merits of the dictionary or classified catalog, analytic indexing of periodicals, indexes for government publications, potential use of bibliographies, and other issues concerning bibliographic organization. Maddox concluded that the most widely discussed library topics of the period, 1876–1885, were classification and cataloging.^[38] The second was the publication of the Dewey Decimal Classification with subject index by the young Amherst librarian. This scheme was designed for a classified catalog and supplied a long-awaited standard index to subjects that would tend to solve one of its major disadvantages. Librarians quickly recognized the value of the scheme, utilizing it first for the classified catalog and later primarily as a shelf arrangement for the dictionary catalog. The third was the planned publication of the *American Library Journal*, which was to serve as "a periodical supplement" to the 1876 Report.^[39] In addition, the editors solicited copies of catalog cards or slips to be used as examples of methods and catalogs in the many libraries and hinted at possible cooperative cataloging ventures by the *Journal* through the "printing of accurate titles of new books in such a way that they can be used for the card catalogs of libraries."^[39] And the fourth was the founding of the Library Bureau, which both standardized the dimensions of the catalog card and later was one of the first organizations to offer printed catalog cards for sale.

The catalog of the Brooklyn Mercantile Library, 1880, was based on the alphabetico-classed concept which

attempted to bring some semblance of order to the subject headings rather than scattering them throughout the dictionary catalog. It occurred at a period when the book catalog was beginning to wane and at a time when the Boston Athenaeum catalog overshadowed other contributions. S. B. Noyes, the compiler, sought a systematic approach to authors, titles, and subjects within a single alphabet by forming certain general classes or class lists, such as BIOGRAPHY (individual subjects), COUNTRIES (alphabetical arrangement), or FICTION (alphabetically by author and title), within the general alphabetical sequence. Specific headings were then grouped primarily under 30 such class lists, which were interspersed among authors, titles, and cross references in traditional alphabetical order. Topics that were too fragmentary, complex, or many-sided would be placed in the general alphabet rather than under the general classes for easy location. Analytics for collections, miscellaneous essays, and some periodical articles were included. The purpose of the catalog was aptly described by Noyes:

The catalogue is designed to secure as far as possible, in one alphabet, an index to authors, titles, class headings, subject class headings, specific subjects and subheads, so that the inquirer may at once be directed to what he is in search of.^[40]

Although it was well received, Cutter criticized the catalog as a “mixture of partial dictionary and incomplete classification. . . .”^[2] The user must know the degree of comprehensiveness of subject, which was generally a varying process as clearly pointed out by Oliver Lilley^[41] in the next century. Cutter further contended that with such classes the arrangement was a “return to the dictionary plan by specific entry,” and certain important classes were lacking which had for instance been used as subjects for a separately published class list for the Lower Hall at Boston Public Library. He conceded that perhaps this irregular selection of classes might “correspond to the public’s unsystematic association of ideas” with the reader possibly looking “in the right place at first” and avoiding extensive use of cross references. He concluded that: “Never the less it may prove a most successful catalogue.”^[2] Nearly 80 years later the comment was made that “its (alphabetico-classed) possibilities have never been adequately explored.”^[30]

The Index-Catalogue of the Library of the Surgeon-General’s Office, 1880–1895, compiled under the direction of John S. Billings, was another monumental product of the period, requiring over 20 years to complete. The title, “index-catalog,” was used to denote the inclusion of books and periodicals. The consistent use of specific headings, which were independent of title words, and a systematic employment of aspect subheadings, which were separated by brackets rather than dashes, were outstanding features of this 16 volume classic.^[29]

Centralized cataloging or the preparation of catalogs or cards by a centralized agency or library for distribution to other libraries was first suggested shortly after the middle of the century by William D. Cooley, an English geographer, and Charles Jewett, through the use of stereotyped plates. Photographic techniques were suggested in 1835 by Albert Blor^[42] and again at the Librarians Conference in 1877 by Henry Stevens, who speculated that centrally produced cards might include a photographically reduced title page for each entry.^[43] F. Max Müller, former librarian at the Bodleian, had suggested the use of printed slips that could be distributed with each book in an article in the *Times* (London) of March 1876. He contended that national libraries should assume the responsibility for cataloging publications produced within their borders and pointed out the desirability of requesting each author to compose a “proper slip of his own book.” He also proposed that printed slips could be used to maintain three or four kinds of catalogs such as alphabetical by authors, chronological, local, and classified by subject.^[44] Similar proposals regarding the use of printed slips had been made by Otis Robinson, librarian at the University of Rochester, 2 years previously, and in 1876 by Justin Winsor, the librarian of Harvard.^[44] The first successful, but short-lived, attempt was by *Publishers’ Weekly* in the form of slips that could be cut apart and pasted on cards. This was followed by a similar venture in 1887 by the American Library Association, which sought to supply cards. The Rudolph Indexing Company in 1893 planned to supply cards for over 100,000 volumes, but this failed to materialize.^[45] The Library Bureau issued cards from 1893 through 1896 until the project was shifted to the American Library Association Publication Section, where it was quickly dropped, although efforts continued through the production of cards for serials and composite books. As the century ended, plans were in the offing to expand the publication of cards by the American Library Association but in July 1898, the Library of Congress began to print catalog cards for American copy-righted books. A short time later cards were exchanged with two or three large libraries, which were also printing catalog cards at that time. A printed card service has been available to all libraries since 1901. Failure of the early attempts at cooperative cataloging was largely attributed to the inability of librarians to accept such a radical innovation; failure of cards to conform to individual practices such as author headings, size of card, and bibliographic information; and the long delays in shipment.^[45]

The early catalogs had occasionally utilized a supplementary alphabetical subject index, which was the forerunner of our present subject lists. After the freeing of subject words from the phraseology of the title, librarians quickly became conscious of the lack of uniformity among the subject headings selected by the various catalogs. The dictionary catalog made the problem even more acute, as now the subject headings were words that would be

suggestive of content, not the title. It was soon observed that they must utilize a syndetic structure to be effective in covering the many possible approaches by the user. A committee was established in 1879 by the American Library Association to study the problem of an index to subject headings that would serve as an appendix to Cutter's *Rules*. Cutter, the chairman, reported 2 years later that an impasse had been reached as "we can't agree."^[46] The efforts of the committee continued with numerous reports and membership changes attesting to the difficulties. In 1895 the project culminated in the publication of the *List of Subject Headings for Use in the Dictionary Catalogue*. The work was a composite listing of terms used by several large catalogs and other sources which had been carefully screened and was complete with "see" and "see also" references. It was considered a standard list for all types of libraries and found wide acceptance in three editions until the final issue in 1911, when it was largely replaced by the Library of Congress list of subject headings, which was issued in parts between 1909 and 1914. The popularity of the latter was assured by the widespread use of printed catalog cards. Its failure to include references until 1943 was a decided drawback, although supplements were a distinct asset in keeping up to date on new terminology.

Three other important bibliographic tools, which would affect catalogs, were issued during this period. The first was the third edition of *Poole's Index to Periodicals Literature*, which extended coverage to 1882. The second was the *A.L.A. Index* of 1893, which was designed to index collections and composite works and free the catalog of innumerable analytics for this type of material. The third was the *Catalog of the A.L.A. Library, 1893*, which was to serve as a selection aid, cataloging guide, and printed catalog. It is interesting to note that all three of these have continued to be issued, although under different names and publishers, until the present time.

Codes: British Museum. Before the merging of the Royal Library with the Cottonian, Harleian, and Sloan collections in 1753, early individual cataloging attempts were as a whole poorly planned and executed. In 1759 the trustees expressed the desirability of a catalog and further suggested in 1807 that a separate alphabetical catalog for each collection be compiled as well as a general classed catalog.^[6] These efforts culminated in the issuance of seven volumes between 1813 and 1819, during the tenure of Sir Henry H. Baber as Keeper of Printed Books.

The current emphasis on scientific classification was skillfully presented by Thomas H. Horne, who submitted his *Outline for the Classification of the Library* in 1825 to the trustees, who engaged Horne temporarily to accomplish such a catalog at the British Museum. Although the project came to an impasse, this proposal and his *Observations on the Manner in Which Titles of Books are to be Entered and Classed* were valuable additions to cataloging

literature. The latter contained a few rules which pertained to bibliographic descriptions such as content notes, forms of authors' names, and the need for several indexes to the classified catalog.

The work on the classified catalog begun by Horne was suspended in 1834, at which time Mr. Baber proposed a plan for an alphabetical author catalog based on 16 rules that provided for uniform cataloging slips, entry under author if it appeared any place in the work, form of name taken from title page, anonymous works placed under "prominent or leading word" with name of possible author inserted at end of titles in brackets, pseudonymous works cataloged under pseudonym with real name inserted after title in brackets, entry under editor for collected works, and translations entered under original author.^[47] In addition he proposed that Panizzi, an impetuous Italian political refugee, should be given the task of editing the new work. The proposal was rejected and then followed by committee studies in 1834 and 1836, during which time the arguments for the classified and alphabetical catalogs were vehemently expressed with few concrete results. In 1837 Panizzi was appointed the Keeper of the Printed Books in spite of strenuous objections. The work on the new catalog was authorized by the trustees in 1838 with a projected completion data of 1840, but with the stipulation that each letter of the alphabet was to be published individually instead of the original "shelf by shelf" plan of Baber and Panizzi.^[6]

The so-called "Ninety-one Rules" employed in the compilation of this catalog were not the work of Panizzi alone but were accomplished by the unique method of having Edward Edwards, J.W. Jones, J.H. Parry, and Thomas Watts compile codes, which were then studied and criticized. The resultant code was thus formulated by the effort of five men who carefully collaborated to express the best in cataloging philosophy of the period. It was approved by the Board of Trustees in 1839 and published 2 years later.^[6] The final product consisted of 91 rather than the originally suggested 79 rules and was decidedly inferior because of the meddling of the trustees.^[48] Work on the catalog, however, was not progressing as smoothly with the first volume so marred by omissions that the printing was suspended in 1841, although the manuscript project continued. A rash of criticisms and investigations in 1847 ensued, with Panizzi defending the "Ninety-one Rules," but now questioning the feasibility of a printed catalog for such a large library. In 1849 a guard book catalog was devised with the entries copied on slips that were formed into a 150-volume catalog by 1851.^[6]

The influence of Panizzi may have been overemphasized, although his impact upon modern cataloging was decisive. An assessment of his contribution is obscured somewhat by the fact that the "Ninety-one Rules" were a product of collaboration, although the testimony before the commissions was assumed to be an expression of his

ideas. He was a fervent supporter of the author catalog, contending that this was the most natural approach by the user. An “index of matter” or title subject words, which were severely limited by the admonition that only the title page was to serve as a source, was appended. The authority of the title page was accepted as a means of attaining a consistent catalog in the typical tradition of the Bodleian Catalogue in 1674. The practice of using abbreviated references which guided the user to the main entry was considered a feasible method of gaining space in the book catalog and set a precedent that would be followed by future librarians even after the advent of the card catalog and the unit card should have negated such a concept. The treatment of anonymous works was a major concern and indicated Panizzi’s feeling that the catalog must be more than a quickly prepared finding list. He sought to separate anonymous works into corporate bodies and form heading groups where possible, still leaving room for those entries that could only be called miscellaneous. The first were arranged in alphabetical order under the name of the country or place “from which they derive their denomination or for want of such denomination, under the name of the place from whence their acts are issued.”^[32] Organizations such as academies, universities, and learned societies were entered under the form heading ACADEMIES, and were subarranged by continent and then country. The second group was designed to place special types of material where form was apparently considered essential under such headings as PERIODICAL PUBLICATIONS, EPHEMERIDES, CATALOGUES, LITURGIES, and BIBLE. The final group was comprised of miscellaneous publications that lacked authors and were not covered in the other categories. They were listed in order of preference as possible alternatives: 1) enter under person if referred to in title, 2) enter under place if referred to in title, 3) enter under substantive if lacking both person or place, and 4) enter under first word if not substantive in title.

This elaborate structure clearly reflected the problem of anonymous publications, which included corporate and miscellaneous works lacking the name of a personal author on the title page. The rules were frequently divergent from Panizzi’s opinions as revealed in the testimony by his preference for the first word that was not an article or a preposition rather than the first substantive,^[32] by his belief that the reader was expected to know the title of the book just as readily as the author,^[32] by his objection to class headings asserting that the most desirable situation would allow every title in its place without any other heading than “its own fixed and certain heading” with fewer titles under each entry,^[32] and by his contention that a cataloger must take the title as it occurs rather than forming it to suit his convenience.^[32] Many of his opponents advocated entry under the subject word rather than the first important word. One of the major contributions of the “Ninety-one Rules” was the concept of placing

corporate bodies under the country or place, although the names were derived from the title and could be construed to have the quality of a subject rather than a corporate author. The system of form headings was a secondary approach relegating special types of works to a consistent location which supposedly made them more accessible than a wide variety of non-descript titles. This approach persisted in British cataloging practices to the twentieth century and was evident in all of the codes including the 1967 Anglo-American code. The reluctance to utilize the conventional title as an entry was evinced by the final group of miscellaneous anonymous work, although it was not indicative of Panizzi’s philosophy.

The “Ninety-one Rules” were a monumental achievement, as they represented the first attempt to codify the rules for the compilation of an author catalog with logical guides for cross references. Many of the basic concepts originated from the Bodleian and other leading libraries. The “Ninety-one Rules” were to form a basis for future codes and had a particular effect upon librarianship in the English-speaking countries.

Codes: Jewett, 1853. The first distinct code of cataloging rules issued in the United States was compiled by Charles C. Jewett, librarian of the Smithsonian Institution. Jewett sought primarily to provide a set of uniform rules established on principles, and supplemented by explanations and examples. The “principal object” of the rules was to secure uniformity; however, he cautioned that even the most elaborate rules were inadequate to “provide for every case of difficulty which may occur.”^[49] About one-third of the publication was devoted to a description of an ingenious system that had originally been proposed in 1850 at a meeting of the American Association for the Advancement of Science in New Haven and again at the Librarians Conference of 1853. Jewett’s plan was truly remarkable for its day as it called for the compilation of a code of rules, the submission of catalog entries by individual libraries according to these rules, stereotyping of each single entry, and the production of catalogs according to demand by simply interfiling and printing. The project failed, however, as it was too far advanced for the period to achieve widespread support as well as being hampered by technical problems that developed in the material used for the stereotype plates. The advantages described by the author were: elimination of duplicate effort, source of location for books, useful bibliographic information, guide for exchange, increased uniformity, possible American bibliography, and a future universal bibliography. The possible list of American literature embodied the concept that was later used in the Library of Congress printed catalogs. He pointed out that copyright books were required by law to be deposited at the Smithsonian and that these could be listed in monthly bulletins, annual lists, and quinquennial catalogs that would form a record of American publications.

He asserted that a catalog was a list of titles of books that a library contained and was generally not expected to give any further information “than the author gives or ought to give in the title page, and the publisher, in the imprint, or colophon; except the designation of form which is almost universally added.”^[49] He admonished that

...the catalog is designed to show what books are contained in a particular collection, and nothing more. Persons in want of further information, are expected to seek for it in bibliographical dictionaries, literary histories, or similar works.^[49]

The alphabetical catalog according to Jewett was the best type and he supported this with many of the arguments previously advanced by Panizzi. He proposed an alphabetical rather than a classified index as it was considered easier to use.

The rules themselves are basically those formulated by Panizzi but with a few changes such as the simplified treatment of anonymous works. The corporate concept was more clearly established in Rule 23 that placed all corporate bodies in one category and provided that they be entered under the name of the body. Cross references were to be made from “any important substantive or adjective, to the principal word.”^[49] U.S. government publications were to be placed under *United States*. To secure uniformity, anonymous works were to be entered under the first word of the title which was not an article with cross references made from other words that might be sought. The librarian would be relieved of problems and the reader would no longer have to search in two places for a book. “Any rule for selecting the most prominent word of a title, or for entering a book under the name of its subject, would be found fatal to uniformity...”^[49] Pseudonymous works were to be placed under the assumed name followed by *pseud* but were not considered pseudonymous if the author had “...published any edition, continuation, or supplement under his name.”^[49]

The contribution of this small pamphlet should not be underestimated. The plea for uniformity would prove to be somewhat idealistic although the suggested rules were widely accepted, exerting a strong influence on future development of catalogs and codes.

Codes: Crestadoro, 1856. Four years after the publication of Jewett’s rules, Andres Crestadoro issued an informative pamphlet^[50] that advocated an extension of the subject word concept. He objected to the classified catalog because of its dependence upon an artificial arrangement and suggested a detailed entry catalog arranged by accession number that would be supplemented by a rather comprehensive alphabetical index of authors and subjects. He believed that the cataloger should add the author, subject, and “nature” or form of each book to the index even though the title failed to yield this information. An

extensive system of cross references was proposed to overcome the lack of standardized terminology by referring from as many terms of the title as necessary, by connecting synonymous terms, and by interrelating class headings with subordinate or “partially synonymous” terms. Title terminology was always preferred with supplied information, only as a last resort supplied by the cataloger. This would scatter similar subjects in several locations, although at least a recognition of the need for a subject approach was expounded.

Codes: Cutter, 1876. The most comprehensive rules formulated during this century were by Charles Cutter. They were issued as part two of the Bureau of Education Report *Public Libraries in the United States...*^[2] The rules evinced the influence of Panizzi, Jewett, Perkins, Abbot, Poole, and other leading librarians of the century. The first edition was issued in 1876 and was continued through a fourth in 1904 that Cutter suggested was actually unnecessary in view of the success of Library of Congress cataloging.^[3] The rules covered the full range of cataloging procedures including a section of definitions; another on entry (where to enter) that contained subsections pertaining to authors, title, subject, and form catalogs as well as analysis; a section on style (how to enter) which included aspects of descriptive cataloging such as headings, body of card, collation, contents, notes, capitalization, and punctuation; and other minor sections pertaining to other catalogs and cataloging of special materials. Some of the major points regarding entry were: entry under personal or corporate author or substitute for it, bodies of men considered as authors, corporate bodies under name, anonymous works entered under title including periodicals, entry under original title for anonymous works when variant titles appear in successive volumes, specific subject heading rather than inclusive class, and subject entry under words expressing content of book rather than under terminology of title.

The rules were the epitome of the cataloging “art” of the period and were complete with copious notes which discussed the problems and suggested possible alternatives. Cutter’s pragmatic approach was based primarily upon three principles. First, was the principle of convenience and habit of the user. System and simplicity should be sacrificed when strict adherence to rules and uniformity create practices which are at odds with the “general and deeply rooted” habits of the public.^[3] Second, was the principle of specific and consistent subject entries. Each term used was to be applicable to innumerable books as it was derived from the content and not the title. It should consist of a specific heading, not the class, to which it was subordinate. To this was added the syndetic structure to connect related and synonymous terms.^[3] Third, the catalog was more than a mere finding list “for a given book by an author’s name” and should facilitate the location of all books of an author by placing them together in one place.^[3]

The rules for the subject catalog represented the first attempt at such a codification and were to serve as the basis of American subject cataloging practices until the present day. Although they were designed to establish principles and practices with alternative solutions, they reflected the occasional uncertainty of the author and are marred by inconsistencies that still haunt cataloging theoreticians today. The Vatican code of 1931 was the only other completed codification of rules for the subject catalog and included one section on general principles and forms and a second on specific areas of application.

Many of the problems of the present dictionary subject catalog may be attributed in part to the context in which Cutter compiled his rules. The book catalog was still the dominant tool although the card catalog was gaining stature and was recognized by his last edition of the *Rules* as the way of the future. The *Rules* were compiled for a book catalog, dependent upon the main entry concept, and were designed for the relatively small popular library with a collection of information sources in the traditionally monographic format rather than the highly specialized texts in varying forms, and promulgated the developing concept of subject analysis that was generally regarded as a convenience rather than a necessity.^[41] The lack of direction that has persisted in the subject catalog may be attributed in part to the unquestioning adherence to Cutter's *Rules* and a failure to expand the few principles that were presented. Similar issues were still visible in the twentieth century when Frarey enumerated the eight major problems of the subject catalog: the principle of specific entry, terminology, form and structure of headings, choice among alternatives (place or subject), confusion of title and entry, size and complexity, reference structure, and maintenance.^[51] Without a doubt, little progress had been made since the days of Cutter except the addition of a new obstacle, the size of the subject catalog that aims at thorough analysis.

The *Rules* as a whole proved to be a valuable addition to library literature and provided a codification of policies so badly needed by American libraries. Many of the issues raised by Cutter were to become the subject of intense debates in the next century. On the negative side the rules supplied a refuge for tradition and tended to reduce cataloging to a routine rather than make it the application of principles. Akers commented that since the 1876 issuance of the *Rules* "...there has been no further development in principles although an enormous amount of work has been done in amplifying, codifying, and clarifying rules, which has contributed to a needed uniformity of practice."^[22]

The nineteenth century had been productive years in catalogs and in cataloging procedures. The beginning of the century found both the classified and alphabetical author catalog in use with a variety of subject arrangements and indexes. Panizzi and Jewett both proclaimed the author catalog the most usable and reasonable form.

The newly developing author catalogs eventually evolved into the dictionary form when subject headings were recognized as independent forms and no longer dependent upon the phraseology of the title page. In 1876 Poole reported that "the plan of the catalogue with references under authors and subjects, in one alphabetical arrangement, is the one which is now most universally used and is preferable to the classified plan."^[52] By 1893 catalog arrangement was still divergent with the single alphabetical order for authors and subject dominating, although some libraries still separated authors and subjects in two distinct parts with the latter in dictionary-classified or alphabetic-classified order. In Europe the classified catalog tended to be more popular, although the subject catalog was never strongly advocated in Great Britain during this century. The Germanic countries tended to develop comprehensive catalogs divided into an alphabetical catalog of authors and anonymous titles and a separate subject catalog or "schlagwortkatalog" that was arranged alphabetically by subject or catchword or the "systematischer katalog" arranged in classified order (logically or alphabetically) by subject.

The form of the catalog was manuscript or printed book at the beginning of the century. The use of slip catalogs, which were maintained originally only for preparation of the printed catalog, slowly began to evolve beyond their original intent. Cards had originally been suggested and used by French libraries in the eighteenth century, but failed to achieve widespread application until expanding book production and changing concepts of bibliographic organization stimulated the need for increased flexibility. Slip catalogs were frequently only accessible to librarians, but the Boston Public Library and the Philadelphia Library Company opened their slip catalogs to public use during the 1850s,^[53] while the former introduced a public card catalog in 1871. By 1893, Lane reported that the card catalog (43 reported) was the dominant form and was conceded a necessity although it infrequently served as a supplement for the printed book (13 reported). He also found that "most libraries still employ a running hand, generally preferring an upright and round to a slanted or angular one."^[54] He reported that the typewriter was now being used by over 40 libraries and that printed cards from the Library Bureau were used by three. He ascertained that catalog cabinet drawers were generally designed for one instead of two rows of cards, which were divided in size between 12.5 × 7.5 cm. (U.S. Postal Card) and 12.5 × 5 cm. although other unusual sizes were in use.

The need for the catalog was now recognized with the subject cataloging evolving from the shelf inventories, to the anonymous title, to the subject word, and eventually the subject heading as advocated by Jewett, Abbot, and Cutter. Lane found a consensus that every book should have an author or title entry and that most should have subject cards. Out of 191 libraries surveyed, 171 reported subject catalogs in one form or another.^[54] Subject

headings were still a matter of catalog's choice and varied widely, but the subject approach to books aided by the syndetic structure was firmly established and awaited further development.

The form of author or title entry progressed considerably during the century. Anonymous works were originally treated by intricate form headings, subject or place entries, or a host of alternatives. Jewett and Cutter advocated the separation of corporate bodies from the anonymous category and established a simple and logical framework. By the end of the century corporate bodies tended to be entered primarily by first word of title or place depending upon the inclusion of the name within the title or whether it was a local British or American group.^[54]

Varying opinions continued to govern pseudonyms at both the beginning and the end of the century.

The entry of descriptive elements had continued to increase. In the book catalog there are wide variations depending upon whether the entry was subject, author, or title as abbreviated forms were used to economize printing space. Lane determined this practice was still present in 1893 even though cards were now widely accepted.^[54]

Throughout the eighteenth century the title page continued to be the basis for the description, with brackets later used to indicate supplied information. The publisher or printer was recognized as an important part of the imprint early in the century. The use of size continued to be standard procedure although methods varied somewhat. Inclusive paging began during the early years and was widely accepted by the end of the century. Editors, translators, and now artists were all recognized as essential parts of the bibliographic description.

By 1893 Lane discerned that libraries tended to agree on the following: diminishing use of capital letters but no uniform practice, Arabic rather than Roman numerals, compound names under last part for English and first part for others, English and French names under prefix, and periodicals under title unless too generic. The use of contents notes evolved more fully during this century and were widely used during the last quarter. Analytics also developed more widespread use as bibliographers sought to increase the usability of the catalog and included periodicals and society publications as in the Harvard card catalog of 1861 and in the Boston Athenaeum Catalog of 1874.

Codes were accepted during this century as the guides for cataloging compilation rather than the individualistic ideas that had dominated. Panizzi, Jewett, and Cutter were the major leaders of the century with Cutter's influence still dominating today's scene. Lane found that the majority of libraries used Cutter, with infrequent or supplemental use of codes by Linderfelt, Library School Rules (Dewey), and ALA.^[54]

The nineteenth century was a period of prodigious growth in cataloging procedures and codification. This

was the era of numerous catalogs beginning with initiatory inventories and finding lists and culminating in the monumental printed dictionary catalogs. American cataloging had passed through a pioneer period while Europeans experienced stabilization. The lack of rules for the construction of catalogs during the early years stimulated local ingenuity, and techniques were crude with uniformity at a minimum. The situation was greatly improved by mid-century, and codes have become a standard part of the cataloging process. The freedom from restraint during this century had nurtured innovative and conflicting ideas, pragmatic and idealistic approaches, and enhanced interest by bibliographers and scholars who slowly began to recognize the necessity for at least some semblance of bibliographic organization. Cataloging activities ceased to be the major concern of the administrators and were relegated to trained practitioners. The differentiation in staff assignments became more pronounced. Cataloging could be considered the first recognized specialization within libraries with Harvard establishing a distinct department devoted to this endeavor in 1859.^[48] Personnel training and recruitment, however, were largely based on expediency for Poole suggested that "there are ladies in the eastern cities who have had much experience in cataloging, and who devote themselves to this speciality. . . ."^[52] The opening of the Columbia School of Library Economy in 1887 assisted development by supplying personnel with previous technical training.

AGE OF SOVEREIGNTY AND SCRUTINY

Modern Period

Twentieth century

The cataloging activities of the twentieth century may be divided into two distinct periods: first, a period of traditionalism which extended approximately to 1941; and second, a period of reevaluation and rebirth.

The survey of cataloging practices by Lane in 1893 was followed by a similar report in the opening years of the new century. He attempted to review some of the then current cataloging tendencies that faced the profession. He began by pointing out that the catalog had been a simple author list but now every library needed as perfect a subject catalog as possible. The debate over the relationship between subject bibliography and subject catalog persisted intermittently when Raynard Swank renewed the discussion in the 1940s. American librarians such as J.C.M. Hanson tended to seek wide coverage for the subject catalog while the European librarians frequently relied heavily upon subject lists. Lane was further concerned by the growing size of the catalog and suggested that certain sections of the catalog could be printed, that selected lists could be compiled for use by the general reader, and that

existing bibliographies could be checked to denote library holdings and to provide for omission of older imprints by libraries attempting to compile a subject catalog. He maintained that classification was used basically as a shelf arrangement, was designed primarily for the popular library, and had contributed little to the subject catalog. He pointed out the values and problems of certain enriching devices of the catalog such as subject headings, annotations, and analytics. He concluded that the card catalog was here to stay although national libraries still relied upon the printed catalog, and that codes tended to “become longer the oftener they are revised,” although the object was to seek simplicity and uniformity with specific instructions for more cases. Lane expressed hope for international uniformity in bibliographic matters and card publication by foreign governments, and he contended that the catalog was a finding list and not a bibliographic dictionary, but expressed the need for cooperation and centralization and described some of the cooperative projects such as printed cards and local union lists of periodicals.^[55]

Two events that were to have a decided effect occurred during the early part of the twentieth century. The reorganization of the Library of Congress revitalized its cataloging department with an influx of qualified personnel such as James Christian Meinert Hanson and Charles Martel who later became leaders in the field of cataloging and classification. The second was the appointment of a committee by ALA in 1901 under the chairmanship of Hanson to revise the old 1883 catalog rules so that they were in accord with those of Library of Congress. A draft or advanced copy was issued a short time later and circulated for comments and criticisms. At the same time the Library Association (Great Britain) was also in the process of revising their cataloging rules and it occurred to Dewey that this was an opportune time to establish some uniformity among the English-speaking countries of the world. A committee was formed and in 1908 the code was completed and published in two separate editions although there were only eight rules upon which agreement could not be achieved. Within the United States the reconciliation of the rules with Library of Congress was not as complete as hoped for; the codification of their practices was still in the developmental stage and efforts had to be continued in this direction.^[56]

Cooperative cataloging, which is defined as the compilation of catalog cards through a joint effort by a number of libraries in an effort to reduce duplication of operations,^[57] continued during this century. The Library of Congress began the printing of catalog cards submitted by other government libraries in 1902, and this was further extended to include several large libraries outside the government structure in 1910. By 1932 the Cooperative Cataloging Committee of the ALA had opened an office at the Library of Congress with a subsidy from the General Education Board. Two years later the Cooperative Cataloging and Classification Service became a division of the

library and by 1941 it was largely absorbed by the Descriptive Cataloging Division.^[58] Efforts at cooperative cataloging were never as intense as those directed toward centralization, which would afford more concentration of staff and tools, maximum standardization of procedures and codification of rules, and substantially improved supervision and administration.

The dictionary form of the catalog continued to dominate the scene with some exceptions such as the 1903 Classed Catalog of the Carnegie Library of Pittsburgh, which was compiled by Margaret Mann and was to be remembered not only for its arrangement but also for its printed format. The debate over the relative merits of the classified and dictionary catalog continued although the issue was largely closed in the United States. In 1905 Fletcher intimated that the dictionary catalog

...has the character of a superstition in so far as it is accepted and religiously carried out on grounds that are traditional, rather than on intelligent conviction that it meets present needs and is good for the future needs for which we must make provisions.

He warned that changes had occurred in the size of libraries, methods of administration, and the attitude toward the library patron that must be considered in catalog construction, and he suggested that the subject catalog be supplemented by the shelf list, bibliographies, reading lists, and indexes.^[59] Rider later renewed the discussion, contending that librarians lacked imagination in approaching the problem of bibliographic organization and should examine such alternatives to the dictionary catalog as the classified catalog, microphotography, book catalogs, and smaller-sized catalog cards. He contended that a philosophy of the catalog was necessary and cited Hanson and Mudge as believing the catalog was an end in itself while Richardson and Currier believed it existed only to put the reader in contact with the library's holdings. He criticized the bibliographic method of cataloging as practiced by the Library of Congress, which was slavishly adhered to by the majority of the libraries in the U.S.^[60] Interest in the classified catalog was somewhat stimulated at an institute on subject analysis of library materials in 1953 when Harry Dewey and Kanardy Taylor supported its excellence. Dewey succinctly outlined the ease of converting the dictionary catalog to the classified.^[61] Kanardy Taylor contended that the alphabetical was best for public use while the classified was more adaptable to scientific research and concluded by agreeing with Gjelsness who contended in 1931 that “perhaps we have gone too far in accepting a standard product and applying it to all purposes” and called for a “universal re-evaluation.”^[62]

Continued interest in the classified catalog in a few special libraries, the mounting pressures for improved bibliographic organization, experimentation with new approaches

to classification, and the recognition of the underdeveloped potential of the classified catalog precipitated the publication of a manual in 1956 that sought to depict the functions, characteristics, and necessary procedures.^[30] Although well done, this manual failed to stimulate the production of classified catalogs, as a survey made in 1962 listed only 16 classified catalogs in use in the United States and Canada.^[63] Today exemplary classified catalogs are found at John Crerar, the Engineering Societies Library of New York, and Boston University Library, and the National Library of Canada. Some libraries did produce duplicate shelf lists, which were used as adjuncts to the dictionary catalog, but further development of the classified catalog in the United States must await another era.

Advocates of the dictionary catalog attempted to facilitate more rapid use and maintenance in the 1940s by separating the subject and form entries and the author and title entries into two distinct files, although other combinations were possible. The separation was reputed to alleviate searching by the user and to make filing by library personnel considerably easier. A number of college and university libraries, such as the University of Denver, adopted the divided catalog but interest was limited with only 24 divided catalogs found out of 457 academic libraries surveyed with the majority of them developing between 1938–1947.^[64] Later the discussion shifted from the author-subject division of the catalog to the horizontal division by date of publication as large research libraries sought to devise a solution to the problem of the mass of entries under some headings.

Size became a topic of discussion as book production soared. The major virtue of the card catalog soon became a detriment as catalogers continued insertion of added entries in the form of analytics, numerous subject headings, title cards, series cards, and catch-titles as well as a host of references for both authors and subjects. Each new edition of the subject lists tended to multiply the number of references until librarians began to question their use. The traditional form of descriptive cataloging continued to necessitate the inclusion of items that some librarians thought should have been relegated to biographical and bibliographic sources outside the catalog.

Library administrators began to bewail high cataloging costs while catalogers struggled to evaluate their methods. As a whole, cataloging departments of the early twentieth century were poorly organized and administered, regimented by tradition rather than by objective analysis of the situation, and dependent upon Library of Congress cataloging practices. To complicate matters the number of catalogs also increased with duplicate cards filed in official, departmental, and union catalogs being maintained at unknown expense. Library of Congress cataloging policies continued to expand with supplementary rules or decisions printed on cards after 1911. Numerous special publications such as a guide for cataloging periodicals

issued in 1918^[65] and another for serials in 1919^[66] were characteristic of the growing complex of rules. The ever increasing arrearage at the Library of Congress, which was due in part to the mass of rules, precipitated an extensive study by Joeckel in 1940.^[67] The survey clearly indicated that the proliferation of rules must be arrested and the present body reduced and simplified. This was followed by further studies during this decade which evinced the desired simplification of cataloging procedures and would reach its climax in the revision of the code a few years later. Librarians were beginning to demand that the principles of cataloging be recognized rather than attempting to provide rules for every situation.

Outside the Library of Congress the use of centrally prepared catalog cards was clearly a time saver, but the constant rechecking and adherence to minutia tended to keep the cataloging costs at a high level. In an effort to counteract the growing size of the card catalog, selective and simplified cataloging were suggested as possible solutions. Selective cataloging was suggested by Dury in 1649 and was thoroughly discussed by Van Hoesen in 1928.^[68] Selective cataloging is an attempt to limit the number of catalog entries by designating library materials for varying degrees according to their potential use. Generally full cataloging is accorded reference works while at the other end of the scale pamphlets or government documents are usually completely excluded from the cataloging process. The economic feasibility of this method was recognized although the cataloger was required to be aware of the users' methods and demands. Simplified cataloging denotes an effort to omit or greatly simplify elements of the catalog card that are not considered essential. It is intended to achieve economy by an abbreviated entry, less effort for verification of author's name, fewer added entries, or similar steps that are not considered essential in a small public library or a childrens' collection. The Library of Congress instituted cataloging categories in 1947 and limited cataloging in 1951. Both are examples of selective and simplified cataloging as certain types of materials were relegated to full bibliographic description while others were described less fully. Added entries were made only after a careful scrutiny of their potential value. In spite of the objection by some catalogers that every book in the library should be subject to the same rules, all libraries practice some form of simplified or selective cataloging. Some innovations are the omission of subject entries for older works, limited use of added entries, and simplified entry for materials in storage. The widespread use of printed cards by commercial companies such as H.W. Wilson and *Library Journal* attest to the acceptance of simplified cataloging by public and school libraries.

The use of the card catalog was also a subject of discussion and represented an attempt to utilize empirical research in offering a more logical approach to one of Cutter's basic principles, the user. Early studies were primarily discussions of inadequacy, complexity, and organization

of catalogs based on traditional impressions and theories of the user and his approach to the catalog.^[69] During the 1930s the studies began to become more concerned with the user's point of view and continued to develop in outlook and method. A survey of 27 catalog use studies completed between 1930–1956 revealed some shortcomings in methodology and tended to relate only to the quantitative use of the catalog. Some of the more significant findings were: catalog used by 50–60% of all library users; nonspecialist tends to use catalog more than specialist; subject catalog infrequently used to find all material in library; English language material of recent date most widely sought; author, title, call number, and subject heading most widely used information; problem of use stems largely from lack of understanding and application of principle of specific entry, preferences for subject or place, and inability to deal with obsolete terminology; subject catalog considered effective about 70% of the time; need for better instruction in use of catalog; and possible modification into a more selective tool as some evidence supports dispensability in present form.^[69]

Active revision of the 1908 code began in 1930 with the appointment of a committee on code revision by the ALA. The preliminary edition of the revised code was issued in 1941 and was divided into two sections: the first dealt with form of entry and heading, and the second was concerned with the description of the book. The code was received with a rash of complaints, largely due to the elaborate rules suggested in part two, which was dropped in the final publication of the second edition. It was immediately apparent that a reevaluation or reappraisal of cataloging policies was needed. This call for reevaluation marked the end of the traditional period and the beginning of the new.

In 1941 the “crisis in cataloging” was succinctly depicted by Andrew D. Osborn who called for an end to the slavish adherence to codes that tended to obscure reasons and principles and maintained that cataloging was an art that was based upon a few simple rules. He continued by discussing the four types of cataloging: legalist theory (an expanding complexity of rules); perfectionism (effort to catalog a book once and for all); bibliographic (cataloging molded into a branch of descriptive bibliography); and pragmatic theory (rules and decisions serving a practical purpose). He soundly condemned the continuance of the three tradition-bound methods and called for recognition of a need for the pragmatic cataloger. He contended that card catalogs frequently failed to achieve their goals because of meaningless practices, a need for three distinct grades of cataloging with the standard less detailed than advocated by the 1908 code, simplified rules even a necessity for the Library of Congress, self-cataloging methods advisable for little-used materials, high quality for essential items but little for nonessential, practical interpretation of any point, and a review of the treatment of serials, documents, and nondocuments to determine cataloging

needs. He concluded that the classical period was drawing to a close and that the change could be largely attributed to extreme systematization and standardization that had resulted from too much work.^[70]

Five years later the report of Herman Henkle on descriptive cataloging by the Library of Congress clearly reflected the changing concepts and sought to develop functions and techniques.^[71] The functions were aimed at presenting an accurate description of each book that would indicate its relationship to other editions and issues as well as entries for other books. The new rules, which were published in 1949, attempted to carry out the proposals of the study with brevity and simplicity.^[72] They were intended as an adjunct to the *ALA Cataloging Rules for Author and Title Entries*, which were finally issued the same year. In spite of the years of discussion and the interest shown in the new codes, they tended to produce only a change in details, with the *ALA Rules* in particular tending to ignore the discussion, rather than reflecting it.^[56] In any event, the period of discussion regarding the codes of 1949 tended to focus concern on the need to reevaluate the function of the catalog, to adapt time-saving methods within the cataloging department, to cope with mass acquisition, and to search for new approaches that would ensure a less pronounced growth of the card catalog.

Within a few years after the appearance of the “twin codes” a movement for the simplification of author and title entries was afoot. The need for guiding principles was examined by Seymour Lubetzky in his study of 1953 that has exerted a major influence upon the actions of the resulting committees.^[73] As in the case of the 1908 code, the activities of the special committees appointed by the ALA were coordinated with a similar committee of the Library Association (Great Britain) and was further augmented by a committee of the Canada Library Association. International cooperation was afforded through the International Conference on Cataloging Principles, Paris, 1961.^[4] The results of the conference were encouraging as a relatively uniform consensus of opinion resulted in a statement of principles pertaining to the function and structure of the catalog and to the choice, form, and structure of entries. These principles clearly reflected the influence of Lubetzky's critique as well as his unfinished draft of 1960^[74] and were accepted by the Catalog Code Revision Committee in 1962. The Paris Principles “were seriously questioned by the large research libraries who were alarmed by the possible extensive recataloging as a result of their retrospective application.” The Library of Congress conducted a detailed study of the “theoretical merits” of the statement and attempted to ascertain the proportion of change required in the retrospective application of the rules in its card catalog.^[75] The results, as expected, provided support for the contention that the large research libraries were unable to accept the radical changes because of the heavy costs of revising the many

catalog entries. The so called “Miami Compromise,” which agreed to certain exceptions regarding the retention of the archaic entry under place rather than name of the corporate body, was approved and incorporated into the code Rules 98 and 99. The Library of Congress accepted the code only as it affects new author headings by adopting the practice of superimposition that allows the new rules to apply only in establishing entries not previously used while reverting to the old rules for all entries presently established in the catalog. As a whole the rules were a significant improvement for they were based upon a set of principles that freed them from some of the rigidity of the past. The inclusion of the rules for descriptive cataloging and for special material provided a single volume rather than the multiple works of the past.

Centralized cataloging became a primary concern during this century. Printed card production was largely limited to a few large public libraries and the Library of Congress. The card distribution service of the latter soon became recognized as a valuable asset with many libraries making extensive use of the somewhat limited number of available cards. In 1938 H.W. Wilson began the printing of catalog cards that were designed primarily for the needs of public and school libraries. The cards followed a simplified system, aimed at providing less bibliographic detail for the more popular titles with annotations and analytics adding another dimension for reading guidance.

The growing need for cataloging information and the dissatisfaction with the present services stimulated the movement for cataloging or processing centers that were occasionally established within large public libraries with small units contracting for services, or at the state level through the efforts of the state library commission, or at the regional level through an association of libraries.

Georgia was the first state library to initiate the distribution of printed cards in 1944. In the following years a number of similar centers were established as were commercial enterprises offering a variety of cataloging services. The major problems of availability and the delay in supplying cards stimulated a large amount of discussion which resulted in a number of cooperative plans such as the one suggested by Ralph Ellsworth in 1948 to assure the availability of printed cards for all books that were acquired by the Library of Congress and cooperating libraries.^[76] In 1953 the Library of Congress inaugurated the All-The-Book Plan in an effort to increase the number of titles for which printed cards were available. The library hoped to solicit prepublication copies of current American imprints from the publishers so that cards would be produced as soon as possible. The Library of Congress order numbers were also supplied to the publishers who placed them on the verso of the title page to assure ready accessibility in ordering cards. The services were further improved in 1959 when R.W. Bowker Co. agreed to lend to the Library of Congress review copies received by them for listing in *Library Journal* and *Publishers' Weekly* in

exchange for cataloging information, which would be included in the latter. Wholesale book dealers and commercial processing centers such as Alanar cooperated by lending copies that were not readily available.^[77] Through this program the bulk of the trade books now had printed catalog cards available. It was estimated that in 1965 Dewey numbers were available in 80% of all Library of Congress printed cards because of this expanded coverage.^[77]

The Library Service Act of 1956 with its state plans and federal funds added further impetus to the development of centers such as the Southwest Missouri Library Services, Inc. in 1957. The trend was apparent for by 1965–1966 there were 63 identified cooperative processing centers in 41 states.^[78]

School libraries enjoyed a similar interest with centralized processing, utilized as early as 1917 in one instance although by 1961 such services had expanded to include at least 3% of the elementary and 2% of the secondary schools.^[79] The National Defense Act and the Elementary and Secondary Education Act of 1965 yielded increased book budgets that in turn actuated the need for cataloging services. Centralized centers for school libraries began to develop as did commercial services ranging from the *Library Journal* kits to complete processing. The charges for standard cataloging by the commercial centers in 1967 varied from \$0.60 to \$1.90, with custom or special cataloging costs much higher.^[80] Card production at the centers and within individual libraries had developed extensively from the early heliotype method mentioned by Cutter in 1876.^[2] A study completed in 1965 outlined the following methods of card procurement or production: purchase, manual typing, stencil duplication (postcard size), fluid duplication, stencil duplication (full size), offset, addressing machine (fiber or metal stencil), automatic typewriter, Diazo duplication, electrostatic copying (Xerox, etc.), defusion transfer copying, and projection photocopying.^[81] To this list may be added the newest computer-produced cards, which are generated by individual libraries as well as being available commercially from the Catalogue Card Corporation of America. Efforts of college and university libraries have been devoted primarily toward improving the program at the Library of Congress although Colorado embarked upon a state processing center. Junior and small 4-year colleges frequently use commercial services in addition to the Library of Congress while infrequently relying upon the state and regional centers.

The Cataloging-in-Source experiment was the revival of a movement that was suggested and attempted during the nineteenth century and was designed to provide a copy of each catalog card within the book itself. The project was conducted by the Library of Congress between June 1958 and February 1959, with over 157 publishers cooperating through the provision of proof copies for 1203 publications.^[42] The plan was well conceived but was

hampered by a variety of factors such as a lack of cooperation by many publishers (only a little over 50% of those originally contacted actually participated) and dissatisfaction with the interrupted production schedules. Some reservations were also evident at the Library of Congress when the projected increases in staff and facilities were questioned in the light of the possible results. The results were well received by the libraries although an extensive consumer reaction survey failed to provide sufficient "clear cut evidence" of possible savings and of utilization of the information. The cataloging information contained in the *Publishers' Weekly* and SACAP, an acquisition and cataloging service instituted by Bro-Dart that would provide paper offset masters suitable for producing a sufficient number of catalog cards, were suggested as more economical methods of obtaining similar results. The project passed into oblivion with the following:

In light of the experience gained through the experiment, it is concluded that neither a full nor a partial Cataloging-in-Source Program is desirable. The *Publishers' Weekly* and SACAP programs have suggested methods by which the potential promise of Cataloging-in-Source might be realized in a much more economical way. There should be no further experiments with Cataloging-in-Source. If the new programs fail to meet their objectives, further experiments should be conducted along the lines these programs have laid down.^[42]

The Cards-with-Books-Program of 1961 was another attempt by the Library of Congress to get cards into the hands of librarians as quickly as possible. The major thrust of the program was to encourage publishers and book wholesalers to supply printed cards with their publications. Special arrangements were made at the Library of Congress to facilitate this operation and by 1967 over 96 wholesale distributors and publishers were annually distributing almost 10 million cards (about two million sets).^[82] Many were still hesitant, however, in spite of the fact that libraries purchase approximately 80–85% of all current American trade books through wholesale book distributors and card sales at the Library of Congress indicate that about 80% of all cards sold are for current American imprints.^[83]

Generally Library of Congress printed cards are available for only about 50% of the research library acquisitions with availability directly related to the acquisition and cataloging efforts of the Library of Congress and the cooperating libraries. The development of the Area Studies programs and the passage of PL 480 created an increased need for catalog cards in a wide variety of foreign languages that were simply beyond the capabilities of most cataloging departments. In 1962 a concerted effort was made to improve the availability of such cards by the Library of Congress adding several language sections to its descriptive cataloging division, with cooperative copy being supplied by large libraries such as Princeton, and

data sheets being compiled by personnel in the country of origin of each publication. A major step toward the systematization of centralized cataloging at the national and international level occurred in 1965 with the passage of the Higher Education Act, Title II-C. The Library of Congress was provided funds in 1966 to embark upon an unprecedented program of worldwide acquisition and centralized national cataloging aimed at alleviating the pressing needs of the research libraries.^[82] The resulting National Program of Acquisitions and Cataloging, known in Europe as the Shared Cataloging Program, was to expedite acquisition through a carefully formulated plan of blanket orders and purchase arrangements. Cataloging operations were accelerated through the use of entries from national bibliographies that provide an international aspect although adjustments were made so that entries complied with existing standards. By the end of the first year of operations nine overseas offices were providing publications from 21 countries with cataloging information from 17 foreign sources.^[82] Catalog cards for over 150,000 publications were supplied to over 92 cooperating libraries in America within the first 12 months of its existence.^[82] The impact of the program will be widely felt by the cooperating libraries as a preliminary analysis of the availability of cards for foreign titles indicated a record high of 73% opposed to the former 50% expectancy while the total number of all titles processed at the Library of Congress rose 20%.^[82] The magnitude of the cataloging operation at the Library of Congress is clearly shown by a reported sale of over 74 million printed cards to approximately 20,000 libraries throughout the world by the Card Division in 1967.^[82]

Centralized cataloging operations were not confined to printed cards only, for in 1965 the Library of Congress published the first reports pertaining to a proposed plan for issuing cataloging information on magnetic tape. The first tapes for this experiment in Machine Readable Cataloging Data (MARC) were issued in November, 1966, to 16 participating libraries and resulted in over 16,000 records for current English-language monographs being provided by the end of the fiscal year.^[82] The results were carefully studied and a more highly developed standardized format was put into operational distribution under the MARC II designation.

Centralized cataloging has experienced tremendous growth during this century. The problems of individualism, time, and limited availability have tended to inhibit the universal acceptance although the situation improved considerably during the last decades. After over 100 years the visionary ideas of Jewett were nearing fruition.

The early 1930s witnessed the establishment of a number of local and regional union catalogs within the United States. The availability of personnel through the Work Project Administration exerted a strong influence upon their proliferation but the ensuing years proved difficult for many of them to endure because of soaring maintenance costs.

Three bibliographic centers at Philadelphia, Denver, and Seattle today attest to the feasibility of the concept. The major reason for the survival of the latter two was probably the establishment of a broad base of regional membership held together by a strong moral belief in the cooperative idea as well as a definite need for such a service within an area rather sparsely populated and without extensive state library collections.^[84]

The most notable union catalog is the National Union Catalog that was established in 1901 at the Library of Congress to provide a listing of governmental libraries in Washington and important libraries outside the city. The reciprocal exchange of cards soon became a reality and depository catalogs were established in many of the major libraries. The growth of the catalog continued and by 1926 it contained more than two million entries. From 1927 to 1932 a grant from John D. Rockefeller, Jr. financed the "Project B" program that was designed to expand the catalog to contain the location of all important reference books in American libraries. After 25 years of administration the Card Division was relieved of the Union Catalog project in 1932 when it was established as a separate unit. Continued efforts by librarians, particularly those working through the ALA, focused attention upon the venture which in turn led to increased financial support so necessary for expansion. The official name, National Union Catalog, was adopted in 1948 and by 1964 over 15 million cards represented approximately eight million titles and editions.^[85]

The pressing problem of maintaining the depository catalogs within the specially selected libraries and the need for wider distribution of cataloging information necessitated a more economical and feasible approach. The most logical solution lay in the revival of the book catalog that had continued as a standard in many national libraries in spite of abandonment by others. A *Catalog of Books Represented by Library of Congress Printed Cards Issued to July 31, 1942* was published in 1942–1946 in 167 volumes and was followed by a series of supplements for both authors and subjects. In 1956 the catalog was expanded to include the holdings of the National Union Catalog and the next issue was given a new title to reflect this increased coverage. The movement to encompass an extended retrospective period led to the publication of *The National Union Catalog, 1952, 1955 Imprints...* and the most recent, *The National Union Catalog, Pre-1956 Imprints*, that is presently being published by Mansell Information Publishing Ltd. (England), and will contain over 16 million cards. Thus the whole spectrum of the National Union Catalog will now be available through the use of the printed book catalog.

The success of the Library of Congress book catalogs and the advent of electronic hardware had a decided effect upon the return of the book catalog. In 1953 the Lamont Library at Harvard produced a printed catalog that was designed for wide distribution to students and faculty.

The catalog was produced by a photo-offset lithographic process such as used by the Library of Congress catalogs, only each of the 40,000 titles were retyped, generally one line per title, in a classified order that was supplemented by an author index of approximately 60 pages and an index of the classification.

The Library and Information Service of Western Australia compiled a classified nonfiction book catalog in 1965 containing approximately 67,000 titles. The classified section was comprised of two volumes arranged by the Dewey Decimal System while the subject index was compiled from the Library of Congress subject headings that were carefully formulated into relative index entries. The entries were typed on strips that were then printed by a photolithographic process. Future revisions are planned by positioning new entries among the original strips.^[86]

A variety of other printing techniques are presently used with varying degrees of success depending upon the desired results and the amount of economic support. The linotype slugs method, used by H.W. Wilson, can be revised simply by interfiling new slugs and removing obsolete ones. It is expensive but is especially well adapted to the cumulative indexing scheme.

The shingled card technique with offset is inexpensive and especially adaptable for the smaller operation. The process entails the photographing of overlapping cards arranged like shingles, preparation of an offset plate from a reduced negative, and final printing. The sequential camera is a refinement of this technique and consists of a special camera capable of photographing only a part of the catalog card as it is placed before the lens. This method was used successfully in 1959 by the National Library of Medicine for the production of its *Current List of Medical Literature*.

The early Library of Congress catalogs utilized a photo-offset process based upon a photographically reduced negative produced by assembling cards immediately after one another in columns. Later a special card was printed which eliminated the blank spaces at the bottom, thus expanding the contents of each page considerably. Another offset process that utilizes microfilm and electrostatic or xerographic reproductions for plate composition has been extensively used by G.K. Hall since 1959 for the reprinting of a wide variety of library catalogs for commercial distribution.

One of the first catalogs produced by tabulating machines was that of the King County Public Library, Seattle, in 1951 and issued on expendable IBM paper. The Los Angeles County Public Library employed a similar approach but went further and prepared multilith masters which were then used to print two extensive and carefully compiled catalogs in 1952 and 1954. The first was a four-volume children's catalog divided into separate alphabets for authors, titles, and subjects and an adult catalog of 37 volumes that was divided into separate alphabets for authors (8 volumes), titles (6 volumes), conventional

subjects (18 volumes), fiction subjects (four volumes), and foreign books (one volume).^[87]

The New York State Catalog of 1956–1960 was designed principally for interlibrary loan and was a single line entry checklist of books and ephemeral material in three broad subjects issued in separate parts. The catalog was produced by the use of a tabulating machine and photo-offset printing.

The Baltimore County Public Library Book Catalog, issued in 1965, was a completely computerized product containing approximately 55,000 titles with bimonthly and annual supplements. The shelf list was arranged in alphabetical order, then edited, and key punched on cards that were later transferred to magnetic tape for storage. The computer organized printout resulted in a divided catalog for authors, titles, and subjects. Simplified cataloging procedures were used as the main emphasis was a finding list rather than a bibliographic tool. Added entries were held to a minimum although no limit was placed on the number of subject headings.^[88]

One computer-produced catalog appeared at Stanford University in 1966 with the first issue of an annual catalog containing about 25,000 titles arranged in a three-part format: author and title, subject, and shelf list. The source of information was the basic Library of Congress cards, which were keypunched and then converted to magnetic tape. The catalog sought to provide “. . . something more than reproductions of unit catalog cards” and rejected both the traditional main entry concept and unit card in an effort to gain space.^[89] The final printouts were photographically reduced and placed on offset masters for printing.

The contemporary book catalog made tremendous strides in the last two decades of its revitalization. Generally production of the book catalogs falls into three categories. First, the photo-offset method based on the production of a photographically reduced negative by shingling or grouping individual cards, by a sequential camera, or by the use of microfilm and electrostatic printing. Second, tabulating machines with punched cards or tape equipment are used to produce printouts or multilith masters. The former may be used as copy for the photo-offset while the latter is immediately available for printing. Third, the computer now is capable of organizing information for catalog production which results in printouts for immediate use or for the production of photo-offset masters. Two other categories should be mentioned although they are an advance beyond the book catalog. First, the use of some form of microprint, suggested by Fremont Rider as early as 1940. Limited production of catalogs that utilize some form of microprint is available although accessibility has hampered extensive use. Another use is in such index-machines as Filmores, Flip, Fosdic, Media, Minicard, Rapid Selector, Verac, and Walnut.^[90] Second, the futuristic computer-stored catalog as depicted by many current experiments may eventually

become economically feasible. Presently the computer input necessary to produce a book catalog could readily be adapted to direct user access and several libraries are making provisions for on-line, real-time terminal inquiries.^[91]

Catalogs and cataloging will continue as in the past to vary considerably from one library to another depending upon needs, former practices, personnel, and financial resources. History clearly indicates that new methods are not unique to this century. A review of some of the so-called recent innovations reveals our debt to the past. The KWIC Index is nothing more than the old subject word concept which was revered by Edwards and criticized by Cutter. The finding list or limited entry catalog was used and strongly supported over 100 years ago by Poole. Arrangement of books in order of accession was practiced even in the most ancient libraries. The use of broad rather than close classification was employed for years. Size classification, so useful in storage libraries, was suggested hundreds of years ago by Gesner. The past can play an important role in future development if new practices are based upon a rational approach stemming from empirical research rather than tradition. The failure to define the functions of the catalog has created a framework of mythology regarding the needs of the users that was further promulgated by Cutter and accepted verbatim by catalogers as gospel. The method used to determine these potential needs during the time of Cutter has never been clearly enumerated although his philosophy has prevailed for almost 100 years and before that was adumbrated by the Bodleian and British Museum Rules which enounced dogma in the same authoritative tones. At that time, however, the position of the library was decidedly different from today as literacy was low and only the gentry had access to printed materials. As the libraries grew and assumed a prominent place in the educational structure, the catalog retained the nineteenth century rules for construction of the printed book catalog while slowly being filled with twentieth century acquisitions. The problem of determining the needs of the user is characterized by an infinite number of variables that are changing every day as the demands of society are modified. The few trends, which are discernible from extant studies, are difficult to translate into action that will fulfill all the needs at reasonable cost. The solution seems to lie in the formulation of catalog-centered criteria, as suggested by Taube, that would provide evaluation based on size, compilation and maintenance costs, amount of appropriate and relevant material, number of access points, extent of information about each item, inclusion of many types of information for various purposes, and a low rate of growth.^[41] These must then be assigned values with regard to the individual library in order to provide a statement of reasonable and attainable functions that can be interpreted into specific goals. The next step is the formulation of methods complete with suitable alternatives. These, however, are not an

end in themselves but serve to carry out the specific goals and more inclusive functions.

It is impossible to foresee the many possible forms and methods which will characterize the catalog of the future because of the infinite variations existing from one library to another. General trends, however, may be conjectured upon the basis of events of the past although levels and extent of applications will vary widely.

The most advanced form of the catalog of the foreseeable future will be the computerized catalog so aptly depicted by Swanson.^[92,93] This catalog will consider 11 performance goals: user dialogues (programmed interrogation), aids to browsing, user-indexed library, access to in-depth information, wheat and chaff identification, national "network" of libraries, national network of bibliographic tools, instant information, remote interrogation and delivery, active dissemination, and quality control over library services (improved feedback).^[92] The basic system would be comprised of two-way communication with a computer-stored catalog such as the National Union Catalog through the use of a console that would permit the user to progress from simple bibliographic or limited subject information through a series of heuristic steps to the actual text. Many of the more specialized works such as periodical articles could be obtained as printouts while the contents of monographs could be examined through a display of the table of contents or indexes by a type of cathode ray tube while the final examination would be dependent upon an actual physical perusal. The plan devotes sufficient attention to all of the performance goals. The cost, based on National Union Catalog size and use, is estimated at about \$50 per minute, clearly prohibitive, with the primary problem created by the disproportionately large amount of information storage to that which is actually used.^[93] The only solution seems to lie in the development of equipment that could economically surmount this problem and the utilization of more complex operations pertaining to subjects rather than simple descriptive searches involving the specific author, title, etc.^[93] The potential use of the computer in providing access to technical reports, government documents, periodical articles, and other highly specialized information has been clearly demonstrated and may be the most economically feasible area of immediate development. The failure of the present subject catalog to go beyond a cursory analysis could be greatly improved through such an application. Libraries will continue to seek wider coverage and will no doubt strengthen their positions through a more thorough subject analysis rather than by concentrating on the traditional monographic sources. Research libraries may find it feasible to store bibliographic information for all sources within the computer and produce printed catalogs only for the monographic materials that will be sought by a large number of users, while the computer information would be available for serious researchers desiring comprehensive searches. The inclusion of actual

textual materials would be limited primarily to the units of a more manageable length rather than attempting to convert to total text storage for extensive monographic material.

A more immediate and universal application of the computer will be the production of book catalogs and catalog cards. As costs are reduced wider application will result in increased regional and national cooperation with catalogs being produced from state or regional union lists in much the same way as from the National Union Catalog. Wide distribution of cataloging information will in turn stimulate more sophisticated methods of card reproduction for those who seek to retain the card catalog.

Aside from the computer, less sweeping but significant changes will probably take place in the immediate future and would be more generally applicable to a large number of libraries. It seems likely that the book catalog will slowly become the dominant manual system with the card catalog serving as a supplement analogous to the old slip catalogs. The dichotomy of expanding the catalog beyond the monograph and limiting it to a reasonable size will continue as a major source of debate. Where computers are available the problem will be a question of input and storage, while both systems will strive to provide more information organized in such a way that the whole file must not be searched for each request. Horizontal division by date will allow older materials to be printed in a separate sequence, and the use of bibliographies will continue to prove useful. The use of the shelf list (conventional or printed) will serve as a source for large blocks of information that can readily be connected by references. The classified catalog will continue to gain new converts like the National Library of Canada where the Library of Congress system is applied. Centrally produced subject indexes for the classified catalog would greatly add to this movement, with several now available through G.K. Hall from such libraries as Boston University and John Crerar although much more needs to be done in this area. Classification will continue to rise above the shelf-location status that it was originally accorded in the United States and serve as a flexible subject device within the catalog. The use of the shelf list will be expanded, serving as a basis for computerization and as an expanded approach to subjects in the manual systems. Terminology will be of primary concern in all types of catalogs with emphasis given to logical development by specialists. Classified subject lists, as suggested by Mostecky,^[94] and thesauri will be prepared to replace the outmoded subject lists with complex and unsuitable terminology set in an illogical syndetic structure. Careful studies, such as those done by Daily, Lilley, and Pettus, all accentuate the need for a more realistic approach to the place of subject headings, descriptors, or indexing terms within the subject catalog. The intellectual process of converting a remote concept into a possible subject heading will be guided by improved lists with heuristic qualities rather than the chance inclusion of

references. The present subject lists have been used to some extent as supplementary guides to the public catalog, but will be eventually replaced by the new lists that will convert the users' concepts into catalog access points. The use of references within the catalog itself could be dropped with the lists serving as the first step to the subject approach. Libraries will continue to expand in-depth subject analysis within the manual systems. Analytics and wider coverage could be accomplished by separate indexes and bibliographies and by improvement of existing sources using a greater degree of more cooperative methods. The service basis approach by H.W. Wilson is indicative of the feasibility and economy of such action. Professional organizations have and should continue to make advances in this direction. Every possible effort should be made to extend cooperative indexing to its fullest potential so that it is available in usable formats, with reduced duplication and increased accessibility to the largest number of possible users. Professional organizations and the federal government will play an active role in such improvements with national planning developing far beyond present levels. Continued centralized efforts such as MEDLAR and MARC will be joined by a host of preparation centers to extend bibliographic control that is much less than popularly supposed. Use of centralized services and decentralized centers will combine a variety of approaches to produce and disseminate the guides to graphic materials. Regional cataloging centers will expand operations with the aid of centrally produced copy. Less deviation will be found between cataloging methods of the various libraries particularly in the areas of descriptive cataloging with a more pragmatic approach overcoming the traditionalism of the past. Major problems of the past will become minor ones of the future with the functions of the catalog clearly placed in a context of simplicity and usefulness.

The literary unit and main entry principle will undergo intensive study that will result in a restatement of their function within the context of the card catalog. The main entry and unit-card concepts have both been eliminated from the computerized catalog, resulting in a substantial saving of space. The literary unit principle will be carried out logically by added entries that may again be accorded new prominence particularly within the computerized catalog. The verification process of the old methods will be modified to meet with a minimum amount of effort. The catalog will perform as a finding list rather than a bio-bibliographical tool which seemed so desirable during the early part of the twentieth century.

Other minor innovations will include a return to the use of guide cards rather than typing subject headings on each card, photographic reproduction of title pages that could be reduced for inclusion on catalog cards or left full size and placed in a loose-leaf binder serving as a supplement, sequential arrangement of books on shelves, and achievement of the original intentions of the *Anglo-*

American Rules with names gaining precedence over locations. In regard to the arrangement of books, it is interesting to note that Dewey originally intended to provide classification numbers that would bring out other subjects of the book and suggested a sequential arrangement of books on the shelves rather than alphabetically by author.

The cataloging operation of the future will be based first upon a succinct statement of functions formulated in the light of needs; second, upon research, reevaluation, and experimentation that constantly provide alternative solutions and new methods; third, upon ideas, concepts, and machinery originating outside the library itself which will aid in the organizational process; fourth, upon professional personnel who plan, direct, develop, and evaluate the program and rely upon technicians who utilize the existing centralized services in the mechanical preparation of a catalog within a planned framework; and fifth, upon the combined cooperative effort of the professional, scholarly, and governmental units which benefit from increased bibliographic accessibility.

The twentieth century may be characterized as a period of growth and development of productivity. The emerging subject catalog developed within the context of the printed book catalog and retained many of the constraints until a new age of librarians began to rise above the technological phases of catalog production. Subject lists developed largely from existing library practices with the profession originating the quest in this direction only to be supplanted by the rather singular effort of the Library of Congress. The fate of the classified catalog was sealed in the United States when the Library of Congress adopted the dictionary catalog that resulted in the issuing of printed unit cards that set the pattern for the whole nation. Research was at a minimum with the appeal to authority exerting an over-powering influence. Catalogers followed the edict of Cutter and debated only his alternative suggestions. The lack of empirical research permitted the catalog to develop with regard only to the book although a secondary effort was given to the periodical indexes, which strangely enough seemed to be outside the realm of the cataloger. The rules employed in the construction of the book catalog were perpetuated in such outmoded practices as the main entry. The card catalog eventually faltered under the weight of the increased number of books being printed with book budgets stretching its size far beyond original expectations. The newly formed administrative librarian, who had only recently relinquished the task of catalog construction to the practitioners, began to complain about the costs of processing. Catalogers sought to evaluate their own procedures but were hampered by traditional functions, outlooks, and methods. The codes continued to grow with each edition until finally the discontents of the 1940s brought some simplification first within the realm of descriptive cataloging that by 1967 had been expanded to include more logical approaches to author headings.

Traditionalism and economic expediency once again caused some attrition but progress was made.

Cooperative and centralized cataloging were given impetus with expanding resources and federal funds largely responsible for their growth because the astute foresight of many librarians focused attention in this area.

The coming of the computer served to answer the immediate needs of the seeker of specialized information and is now being applied to conventional library situations with varying degrees of success. Its place in future development is apparent and is dependent upon pecuniary resources and logical applications.

By mid-century the subject catalog was the subject of considerable debate. User studies have failed to provide concrete answers for all situations but generally have indicated trends that aided in selecting methods. The role of the subject catalog, though generally recognized, has undergone more intensive study with its components, such as subject headings and the syndetic structure, receiving considerable attention. The results have been rewarding in a limited degree with some understanding gained through analytic studies of subject terminology and a burgeoning number of special subject lists or thesauri. Libraries, like other social institutions, have failed to keep up with new innovations and as a whole have retained old methods or hastily accepted practices that lead to unendurable problems. The subject catalog will continue to demand major emphasis during the remainder of the century that hopefully will be marked by scientifically sound experimentation and rational development.

CONCLUSION

The unfolding of the story of catalogs and cataloging has indicated general trends, which may be succinctly summarized. The ancient period was a time of crude inventory lists that served only as a listing of property rather than an index to the library. The contributions of Callimachus to the cataloging field were typical of the early bibliographic endeavors that were prepared by scholars in order to preserve a record of the leading literary works of the period. This method was characteristic of the attempts of the ancient civilizations that sought to perpetuate the culture for ensuing generations. The concept of authorship and title was confusing, with listings frequently a combination of author names, titles, and/or first lines although the Greeks were probably responsible for the use of the author in reference to individual works. Chronology or order of accession were the primary orders of arrangement. The rise of Christianity shifted the centers of learning to the monasteries where the codex was used and reproduced for distribution to other religious houses. Books were an exceedingly valuable commodity which necessitated a record of the holdings of each collection. Slowly the lists began to reflect a utilitarian aspect with

books arranged not by the old chronological approach but by order of importance to the user that in turn led to broad subject and form arrangements persisting for many centuries and later forming the basis for the more systematic classification schemes. As these lists lacked author or subject, and title indexes, they were not catalogs in the modern sense of the word but rather resembled our shelf list in character and use.

In the thirteenth century the first union catalog was attempted and college and university libraries, which were to exert such an influence on later development, began to assemble comprehensive collections.

The fourteenth century brought the inclusion of an author index appended to an inventory list that could conceivably be designated as a true catalog.

The fifteenth century with the invention of movable metal type brought a new need for bibliographic organization with leaders such as Trithem who appended an index of authors to his chronologically arranged bibliography of ecclesiastical writers and exhibited a concept of the main and added entry which was further developed by Gesner, Trefferus, Maunsell, and Sir Thomas Bodley.

The sixteenth century was marked by a number of leading bibliographies produced by Gesner and Maunsell who were joined by Trefferus in providing information on the construction of catalogs. Two astute bibliographers suggested that a bibliography could be pressed into service as a substitute for the catalog. Maunsell's use of the author's surname was indicative of the changing concepts regarding names. The addition of supplementary indexes was clearly emerging with the number of access points going far beyond the original inventory list and catalogs beginning to assume the retrieval function.

The seventeenth century brought the Bodleian catalogs. The author arrangement of the influential issue of 1620 advanced the concept of entry with considerable attention to the determination of the form of main entry and an expression of the literary unit principle. An early form of the dictionary catalog with authors and subjects filed in a single alphabet appeared although the single entry (author or title for anonymous) was the rule of the day. A number of codes of instructions by Naude, Dury, and Baillet indicated that interest in the catalog was increasing with methods taking on a few primitive signs of standardization.

The eighteenth century found a national cataloging project in France using cards as a basis of the catalog as well as a national cataloging code. Bibliographical description slowly increased and was assuming more of its modern aspects.

The nineteenth century was the high point of cataloging with a number of important codes produced, beginning with the British Museum and reaching a zenith in Cutter's *Rules* of 1876. Catalogs steadily developed under the concept of the subject word particularly within Germany and America as the single entry idea expanded beyond

conventional application. The card catalog became more commonplace after 1860 and assumed a variety of arrangements reflecting a number of divergent opinions. The subject catalog was the major contribution of the era and was employed first in America by Jewett. Cutter was to provide the definitive work with the publication of his *Rules* in 1876, which were to serve for years as authoritative and final. The problem of catalog arrangement was still a controversial issue at this time and was never satisfactorily resolved, although, elements of the classified printed book catalog were readily adopted to the dictionary card form. The emergence of centralized cataloging at the Library of Congress, which was based upon a dictionary catalog, terminated serious debate and elevated the technological aspects of its catalog to a paramount place with little regard for its philosophical advantages over the classified systems.^[41] Classification became not a tool of the catalog but rather a location symbol. The catalog was dependent upon an alphabetical order which was supported by a syndetic structure, serving as a systematic guide to subject terminology. Subject headings and cross references, however, grew not by design but rather by chance until the burgeoning size of the catalog brought forth a deluge of criticism against Cutter's answer to the classified catalog. The lack of an acceptable classification scheme no doubt influenced the rapid growth of the dictionary catalog, which came under close scrutiny during the twentieth century. The overemphasis on rules and a preoccupation with monographs in libraries stymied innovation to such an extent that seekers of specialized information and extraordinary services turned first to the documentalist and then to the information scientists. The mid-fifties produced a number of studies pertaining to the classified catalog, approaches and needs of the user, cost analysis, catalog division, book catalogs, and the relationship of bibliographies to the catalog. All of these reflected the failure to adequately study the fundamental design and purpose of the alphabetical subject catalog in card form.^[41] By the end of the nineteenth century the pattern of catalog construction was well defined with subject headings, main entry, literary unit principle, dictionary catalog, classification, unit cards, added entries, and adequate bibliographical descriptions all well-developed elements. Cooperative cataloging was in its beginning stage with the first efforts directed toward an early type of cataloging-in-source, which advocated slips with the books.

The twentieth century brought an expansion of cooperative and centralized cataloging, three new cataloging codes for the English speaking world, numerous subject lists, and a general reevaluation of the cataloging process beginning with the descriptive phase. The junglelike growth in the size of library collections forced many librarians to seek simplified methods as well as expanding cooperative and centralized services.

Substantial sums of money have been used since the intervention of the federal government into the field of

scientific information with primary efforts directed toward retrieval of specialized information but later expanding to encompass services of more immediate value to public and research libraries. The National Program of Acquisitions and Cataloging Program is one example of the concerted effort which will result in a more comprehensive coverage of printed cards for foreign titles and will stimulate international cooperation in bibliographic control.

Continued technological advancements such as the electric typewriter, electrostatic copying, telefacsimile transmission, and computers will expedite cataloging activities.

The present and future hold great promise for the development of catalogs into a more useful, more functional, and more comprehensive tool through the formulation of attainable goals, continued experimentation, empirical research, and cooperative effort. So far there is no indication that the need for catalogs will ever diminish or be replaced.

APPENDIX LIST OF CODES OF CATALOGING RULES

- 1791 *Instruction pour procéder a la confection du catalogue de chacune des bibliotheques sur lesquelles les Directoires ont dû ou doivent incessamment apposer les scelles* Imprimerie nationale, Paris, 1791.
- 1841 *The British Museum code of ninety-one rules*, adopted by the Trustees in 1839.
- 1852 C.C. Jewett, *Smithsonian report on the construction of catalogues of libraries. . .and their publication by means of separate, stereotyped titles, with rules and examples*.
- 1876 C.A. Cutter, *Rules for a printed dictionary catalog*. (Revised in 1889, 1891, and 1904.)
- 1878 Cambridge University, *Rules to be observed in forming the alphabetical catalogue of printed books*. (Originally contained 49 Rules but enlarged to 64 in 1925.)
- 1878 *L'Instruction general erelative au service des bibliotheques universitaires*.
- 1883 American Library Association, *Condensed rules for an author and title-catalog*.
- 1883 Oxford, Bodleian Library. *Compendious cataloging rules for the author catalog*.
- 1883 Library Association, *Cataloguing rules*.
- 1884 F.B. Perkins, *San Francisco cataloguing for public libraries*.
- 1886 American Library Association, *Condensed rules for a card catalog*.
- 1886 K. Dziatzko, *Instruction fur die Ordnung der Titel im alphabetischen Zettelkatalog der Konigl, und Universitatsbibliothek zu Breslau*.

- 1888 M. Dewey, *Rules for author and classed catalogs as used in Columbia College Library*.
- 1889 L. Delisle, *Instructions elementaires et techniques pour la mise et le maintien en ordre des livres d'une bibliotheque*.
- 1889 M. Dewey, *Library school card catalog rules; with 52 facsimiles of sample cards for author and classed catalogs*.
- 1890 L. Delisle, *Instructions elementaires et techniques pour la mise et le maintien en ordre des livres d'une bibliotheque*, Lille, 1890.
- 1890 K. Linderfelt, *Eclectic card catalog rules; author and title entires based on Dziatzko's "Instruction" compared with the rules of the British Museum, Cutter, Dewey, Perkins and other authorities*, Boston, 1890.
- 1899 Prussia, *Instruktionen fur die alphabetischen Kataloge der preussischen Bibliotheken, vom 1899. Zweite ausgabe*, 1908.
- 1902 Spain, *Junta facultativa de archivos, bibliotecas y museos*, Madrid.
- 1905 United States, Library of Congress, Catalog division. *Supplementary rules on cataloguing*. (First published as a monograph but continued on cards.)
- 1908 American and British Library Associations, *Cataloguing rules; author and title entries*.
- 1909 *Instruktionen fur die alphabetischen Kataloge der preussischen Bibliotheken vom 10. mai 1889. 2. ausg. in der fassung vom 10. August 1908*. Berlin.
- 1912 Association des Bibliothecaires Francais, *Regles et usages observes dans les principales bibliotheques de Paris...*
- 1912 French Library Association, *Regles et usages observés dans les principales bibliotheques de Paris pour la rédaction et le classement des catalogues d'auteurs et d'anonymes*, 1912.
- 1913 Association Des bibliothecaires francais, *...Regles et usages observés dans les principales bibliotheques de Paris pour la rédaction et le classement des catalogues d'auteurs et d'anonymes (1912)...*, Paris.
- 1916 Sweden, Kungliga biblioteket, *Katalogregler for Kungl, biblioteket samt anvisningar for anordnande av bokband*, Av riksbibliotekarien faststallda den 30 juni 1916, Stockholm.
- 1917 Denmark, Bogsamlingskomite, *Katalogisering; raad og regler til brug ved ordningen af bogsamlinger, udgivet af Statens bogsamlings-komite*, Copenhagen, 1917.
- 1921 Norway, Norsk bibliotekforening, *Forslag til katalogiseringsregler utarb. av Norsk bibliotekforenings katalogkomite*, Christiania, 1921.
- 1921 Vereinigung schweizerischer bibliothekare, *Entwurf zu einer Katalogisierungsinstruktion fur den schweizerischen Gesamtkatalog*, Zurich, 1921.
- 1922 Italy, Commissione incaricata di progorre un nuovo codice di regole (etc.), *Regole per la compilazione del catalogo alfabetico*, Rome, 1922.
- 1922 Bayerische staabsbibliothek, *Katalogisierung-sordnung. 2. ausg.*, Munich, 1922.
- 1922 Bodleian Library, *...Rules for the cataloguing of printed books published before 1920...*, Oxford, 1922.
- 1923 France, Bibliotheque nationale, *Usages suivis dans la redaction du Catalogue general des livres imprimes de la Bibliotheque nationale, recueillis et coordonnes par E.G. Ledos*, Paris, 1923.
- 1925 Norway, Norsk bibliotekforening, *Katalogiseringsregler for norske biblioteker utarb. av Norsk bibliotekforenings katalogkomite*, Oslo, 1925.
- 1929 Association des Bibliothecaires Francais, *Regles generales*.
- 1931 The Vatican code, *Norme per il catalogo degli stampati*.
- 1936 *Rules for compiling the catalogues of printed books, maps and music in the British Museum*. Revised edition.
- 1941 A.L.A. *Catalog rules: author and title entries*, prepared by the Catalog Code Revision Committee of the American Library Association, with the collaboration of a Committee of the (British) Library Association.
- 1949 A.L.A. *Cataloging rules for author and title*, 2nd ed., ALA, Chicago, 1949.
- 1949 U.S. Library of Congress, *Rules for descriptive cataloguing in the Library of Congress*, Government Printing Office, Washington, D.C., 1949.
- 1961 Germany (Federal Republic), Bundestag, *Instruktionen fur die Kataloge der Bibliothek des deutschen Bundestages*, 1961.
- 1961 U.S.S.R., *Glavone upravlenie kul'turno-prosvetitel'nykh uchrezhdenii. Edinye pravila opisaniia proizvedenii pechati dlia biblioteknykh katalogov*. Chast' I. Vypusk 2. *Organizatsiia alfavitnogo Kataloga knig*, 2-e izdanie, ispravlennoe i dopolnennoe. (Standard rules for the description of printed works for library catalogs. Pt. 1, Section 2; Arrangement of the alphabetical catalog of books. 2nd ed., rev. enl.), Biblioteka im. Lenina, Moscow, 1961.
- 1964 Spain, Direccion General de Archivos y Bibliotecas, *Instrucciones para la redaccion del catálogo alfabético de autores y obras anónimas en las bibliotecas publicas del estado, dirigidas por el Cuerpo Facultativo de Archiveros, Bibliotecarios y Arqueólogos*, 3 ed. reformata, Dir. Gen. de Archivos y Bibliotecas, Madrid, 1964.
- 1965 Verein Deutscher Bibliothekar, Kommission fur alphabetische Katalogisierung, *Regeln fur die alphabetische Katalogisierung. Teilentwurf*.

Kolstermann, Frankfurt, 1965. (A partial compilation of a new German code with Part I pertaining to corporate authorship and Part II covering alphabetical arrangement. This work clearly indicates the Paris principles.)

- 1965 Japanese Library Association, *Nippon Cataloguing Rules*, 1965. (This extensive code was clearly influenced by the Paris principles.)
- 1965 Zentralinstitut für Bibliothekswesen, *Titelaufnahme für die Kataloge der allgemeinen bildenden Bibliotheken*, 2nd rev. ed., Bibliographisches Institut, Leipzig, 1965. (The Paris principles have strongly influenced this code although corporate bodies are not recognized as main entries.)
- 1967 *Anglo-American cataloging rules*, prepared by the American Library Association, The Library of Congress, The Library Association and the Canadian Library Association, ALA, Chicago, 1967.

Censorship and Content Regulation of the Internet

Peng Hwa Ang

Wee Kim Wee School of Communication and Information, Nanyang Technological University, Singapore,

Abstract

Censorship is defined as the intervention by a third party between the free exchange of a willing sender and a willing receiver of information; typically, censorship is repressive in that both sender and receiver do not want the intervention. Censorship of the Internet began clumsily from when it was made publicly available. Then governments were trying to reconcile the new medium with existing rules on traditional media. Since then, there have been two other overlapping and parallel waves of attempts to censor Internet content. Today's censorship of the Internet is more nuanced. Governments in general do not accept the argument that the Internet is difficult to censor. Among the methods used are simple denial of access to the Internet, passing punitive laws that would deter others when those who are caught are prosecuted, and using blocking technology. The most acceptable face of such censorship would be for the protection of minors and through filtering of the Internet. Censorship of the Internet will continue to exist because of the cultural differences that exist.

INTRODUCTION

For many years after it was introduced to the public, it was held as a self-evident truth that the Internet could not be censored or regulated. The sentiment was first pronounced by John Gilmore in 1993, before the Internet became widely available to the public, the "Net treats censorship as damage and routes around it."^[1] It was reiterated by John Perry Barlow in his Declaration of Cyberspace that governments have no place in cyberspace.^[2]

One of the reasons is that the Internet has a diffused packet-switching architecture that was absent any visible central governing body that regulated it on a daily operational basis. It seemed designed to evade government control. If there was a slogan then, it would have been "information wants to be free."^[3]

Scholars such as David Johnson and David Post argued that the Internet could not be governed by existing legal regimes because it crossed borders.^[4] The U.S. government under President Bill Clinton declared a hands-off approach to Internet communication and e-commerce because of its "decentralized nature and... tradition of bottom-up governance."^[5]

The Internet has come a long way. As at November 2007, there were an estimated 1.3 billion users, almost 20% of all inhabitants on the planet, and the number is still rising.^[6] The evidence is overwhelming today that neither the architecture nor the lack of a visible central governing body necessarily means the Internet is beyond government control.^[7,8] The Final Report of the Working Group on Internet Governance shows that there is a need for a central body to at least coordinate the Internet for it to function.^[9] This is the Internet Corporation for Assigned Names and Numbers (ICANN). While ICANN cannot be accused of

censorship, the fact that it is located in the United States gave rise to the issue of what happens when the United States is at war with another country. What happens to the Internet in the other country? Before the war in Iraq, the operators of the Iraqi domain name .IQ, who were based in Texas, were arrested and charged with unauthorized sale of computer parts to fund terrorist groups. The operators were eventually convicted in 2005 and 2007.^[10]

It was at the World Summit on the Information Society (WSIS) in Tunis to discuss the Report of the Working Group on Internet Governance (WGIG) that it was agreed by all the countries present, including the United States, that the country code top level domain (ccTLD) system would be managed only by the country themselves. In the case of the .AF domain name for Afghanistan, the private individual who held the right to operate it signed his right away to the new government in 2004.^[11] The WSIS Declaration in Tunis implicitly recognizes the sovereignty of national government over the Internet. The long arm of national laws can reach into the realm of Web site content; it is possible, within limits, for governments to control the Internet.^[12]

Another group that has shown interest in gaining some measure of control over the Internet is the private sector. If information ever wanted to be free, the providers did not. Increasingly, content is being copyrighted. Government regulation is necessary to balance the rights of individual to privacy and fair use of information with the desires of the private corporation.

DEFINITION OF CENSORSHIP

A working definition of censorship by this author is: the intervention by a third party between the free exchange of

a willing sender and a willing receiver of information; typically, censorship is repressive in that both sender and receiver do not want the intervention.

There are a few points to note about the above definition. First, the definition of censorship is independent of the party. This is in contrast to the position in some countries, such as the United States under the First Amendment to its Constitution, the government shall “pass no law” abridging content. This means that in the United States and in countries that have similar phrasing in their constitutions, the governments cannot, subject to qualifications by the courts, censor content. Business, however, is not subject to the same restrictions placed on government.

An example of such a divide would be, say, a song with lyrics calling the police “pigs.” In many countries, such lyrics would be banned by law because they encourage the flouting of law and order. In the United States, however, such lyrics would be allowed but business may refuse to carry the music and other groups may encourage boycott of the singer of the song.

Second, it excludes such acts as editing, which seeks to improve the meaning and clarity of the message. The definition may or may not include gatekeeping functions, such as which messages should appear and in what order. In those instances, it is not always clear if there are legitimate grounds for gatekeeping or if it is censorship—in the sense of intervention with the primary intent of blocking the transmission and reception of the information.

Third, the definition includes what is sometimes called “pre-censorship.” As practiced on traditional print and broadcast media, censorship involves the removal or deletion of forbidden material. With the Internet, it is often not possible to remove or delete material from a Web site. Instead, the most frequently used method is to deny, block, or filter access. To distinguish the act of removal, some call such denial of access “precensorship.” The distinction, however, is not helpful and in fact disguises the fact that censorship is at its most egregious when the content is blocked even before it sees the light of day.

Sometimes, what may be censorship to one person is to another perfectly legitimate, perhaps even backed up by law. For example, the European Union lists as grounds for restricting information that are “potentially harmful or illegal contents or can be misused as a vehicle for criminal activities” the following:

- National security (instructions on bomb-making, illegal drug production, terrorist activities).
- Protection of minors (abusive forms of marketing, violence, pornography).
- Protection of human dignity (incitement to racial hatred or racial discrimination).
- Economic security (fraud, instructions on pirating credit cards).
- Information security (malicious hacking).

- Protection of privacy (unauthorized communication of personal data, electronic harassment).
- Protection of reputation (libel, unlawful comparative advertising).
- Intellectual property (unauthorized distribution of copyrighted works, e.g., software or music).^[13]

That list includes restricting information that violates privacy, reputation, and intellectual property rights. In general, most countries around the world would consider the restrictions acceptable and be legal under law. The United States, because of its First Amendment, would be an outlier in this regard. For example, hate speech, such as the denial of the Holocaust, is allowed under the United States and the government would not be able to censor them on the Internet. In practice, however, there would be pressure from business and civil society exerted on the hosts to remove such offensive material. Often, such pressure can be effective.

HISTORY

Early Days

Since the diffusion of the Internet to the public, three overlapping and parallel “waves” of attempts to regulate Internet content may be discerned. The waves reflect the attempts of national governments and international agencies to wrestle with the Internet. In the first wave, from 1994 to 1997 in the early days of the Internet, the approach was to attempt to fit the Internet into the same mold as traditional mass media. That is, governments used legislation and existent executive powers and resources that most closely resembled that part of the Internet to regulate it. If that part of the Internet functioned like a newspaper, then newspaper laws applied; if another part functioned as a broadcasting station, then broadcast rules applied. This “functional approach” to regulating the Internet is understandable because lawyers and judges are trained to use precedents and analogies in their arguments.

In South Korea, the offline rules pertaining to national security were imported to apply to the Internet.^[14] Under the National Security Law, any publication that praised North Korea would be banned. So when one page of the massive Geocities Web site praised the North Korean leader Kim Il Sung, South Korea blocked access to the entire Geocities site.^[15] After a hailstorm of international criticism that followed that incident, South Korea removed that block and has not attempted a similar move.

When Singapore made Internet access publicly available, it was the first country in the world to develop a code of practice for Web site owners in 1996 but also the first to have an official government Web site (<http://www.sg>). It was, however, the code of practice that drew worldwide attention, because it was the first Internet-specific

legislation aimed at regulating content. The code empowered the authorities to block for residential users some 100 mostly pornographic sites using a proxy server; experts said the proxy server could block up to 300 sites after which the user would notice the slowed access. The code also licensed Web site owners, in line with Singapore rules that require licensing of all who publish any periodicals. The license would be revoked if the terms for them were breached. In a nod that recognized the uniqueness of the Internet, licenses were automatically issued—that is one was given a license when one operated a Web site.^[16] Why was this fiction of an automatic “class license” created when it is well-nigh possible to just have a law that criminalized the breach of the rules in the code? Functionally, the Singapore regulators were treating the Internet as a traditional mass medium: anyone who ran a mass medium in Singapore had to have a license.

Meanwhile in the West, governments were attempting to apply rules to the Internet to combat credit card fraud, pornography, etc concerning the Net, as was reported in the news then. It was as if Prometheus had brought back fire and all that the media covered were people getting burned by it. One incident that marked this feverish pitch was the *Time* magazine cover story of July 3, 1995, in which the magazine said that more than 80% of the images posted on Usenet newsgroups were pornographic.^[17] The study was later discredited.

Inevitably, there was pressure on politicians “to do something.” Laws were passed hastily. In the United States, the U.S. Supreme Court struck down a part of the Communications Decency Act in 1997.^[18] Across the Atlantic, a similar fate befell a comparable law in France. In 1996, the French Constitutional Council struck down provisions of a new Telecommunications Law that empowered the Conseil Supérieur de la Télématique to make recommendations on what types of content was permissible.^[14]

In short, between 1995 and 1996, it looked as if the Internet would never be regulated. Countries that were trying to regulate it were either failing before the courts or failing in practice. Singapore was giving it a shot but in essence, it was not really doing much. Laws in the United States and France were being struck down. In the conceptual space, scholars such as Post and Johnson suggested that the Internet needed a new legal regime and the United States said that it was taking a more hands-off approach to regulation.

Latter Days

Law enforcement, however, was not taking a similar approach. Australia, which had probably the soundest Internet policies at that time, conducted a sweep for consumer fraud in 1996. No new Internet laws were passed for the sweep. Instead, the consumer protection agency relied on existent laws. Since then, a number of countries,

including the United States, have joined Australia in conducting such annual sweeps under an umbrella organization called International Consumer Protection and Enforcement Network (ICPEN).^[19]

Similar sweeps have also been mounted against child pornography. Cyber libertarians say the Net is ungovernable because effective regulation requires international cooperation and such cooperation is difficult to come by. For example, what is a crime in one country may not be a crime in another. There is one offence that virtually all countries can agree upon—the use of children for pornography. (Japan had to pass child porn laws in May 1999 to be in line with international norms; until then, the Japanese drew no distinction between porn of children and adults.^[20]) In a sweep called Operation Cathedral, police in 14 countries in the OECD cooperated to crack several child-porn rings.^[21] Today, child porn is an area that police patrol.

On the legislative front, with direct regulation failing before constitutional challenges, attention turned toward self-regulation. It appeared that a prevalent notion was that self-regulation was *the only* way to regulate the Internet. In 1998, the Internet Law and Policy Forum, an independent and loose association formed mainly of lawyers, initiated an effort to look at self-regulation. Its Web site carried a bibliography that appeared to signal the start of a serious study on the subject of self-regulation.^[22] Unfortunately, the study appeared to have been stuck at that starting line of 1998.

From 2000

Around the turn of the millennium, two trends toward regulation were discernable: self-regulation and direct regulation. The Internet industry has been reluctant to self-regulate. The U.S. Federal Trades Commission, after giving several one-year deadlines for the industry to regulate the privacy of children using the Net, passed the Children Online Privacy Protection Act in 2000.^[23] In Australia, the Internet Industry Association emerged with a code of practice after five fruitless years when the Federal government passed a law that, among other things, compelled the development of the code.^[24] The Federal law has forced some sites to move from Australia.^[25]

In Europe, there has been some movement toward self-regulation. Internet Service Providers' associations have often developed codes to minimize their own liability as well as to self-regulate some aspects of business. This contrasts with the United States, which is suspicious of codes, and Asia, which lacks cohesive industry associations. The movement toward self-regulation in Europe has been aided by the work of the Bertelsmann Foundation.^[26]

In 1999, the Foundation, started by one of the world's largest book publishing houses, brought together a group of experts to address the issue of content filtering. The Internet Content Rating Association (ICRA) filtering

platform based on platform for Internet content selection (PICS) was launched a year later. ICRA, an effort with which the author was involved, aimed to empower parents with simple tools to filter contents of Web sites while addressing the charge of censorship. American civil libertarian groups such as the American Civil Liberties Union (ACLU) and the Center for Democracy and Technology (CDT) were among various bodies consulted during the development of the platform. ICRA's idea was simple: Web sites were to tag every page; users were then to decide what content they would allow. Although it did succeed in creating a filter that was acceptable for the most part by civil libertarians because tagging was not compulsory, ICRA did not succeed in getting the tool to be incorporated into Web browsers. An attempt to develop a plug-in failed. The result was that it was never in use. In February 2007, ICRA relaunched itself as the Family Online Safety Institute (FOSI).^[27]

The Western European experiment in self-regulation is commendable but appears to have blunted by the reality that it is limited in practice. Nevertheless, Western Europe may well play a significant leadership role in the laws and policies of regulating the Internet. There are several reasons for this.

In general, many Western European countries acknowledge some degree of censorship of some media content. This position more closely resembles the situation in many parts of the world where censorship is present, varying only in degree.

On the other hand, many European countries also protect free expression under Article 10 of the Council of Europe's convention on human rights, more formally known as the Convention for the Protection of Human Rights and Fundamental Freedoms.^[28] This protection resembles the U.S. First Amendment as well the culture of Internet users. In short, Europe has checks and balances on the competing interests of censorship and free expression.

Against this backdrop, there have been surprising developments in the Western European countries. In 2000, a French court ordered the Internet search-engine Yahoo to block French users from accessing a section of the site that auctioned Nazi memorabilia.^[29] Although Yahoo initially objected, it later banned the sale of Nazi and hate-related material on its site.^[30] To be sure, there are peculiarities in the case. First, Yahoo had used a French domain name—yahoo.fr. That gave the French a jurisdictional toehold on Yahoo. Second, Yahoo was targeting the French users through its advertising. So when Yahoo said it had no way to filter out users the judge was unconvinced: if French users could be directed to a French version of Yahoo, surely Yahoo could filter its users to deny them access to Nazi memorabilia. The information on which the judge based the findings had been given by a panel of experts that included Internet-pioneer Vinton

Cerf. The experts, however, did not agree with the conclusion of the judge on ideological (the Internet should be free) and pragmatic (the filtering was only about 70% effective anyway) grounds. The ideological ground is impossible to explain away. But the pragmatic ground reflects a deficient understanding of the purpose of censorship—it is not meant to be 100% effective.

This is a form of what economists call the “Nirvana fallacy”—something is not worth doing if it does not achieve perfect results. For example, an argument often made against censorship is that on the Internet, a user can always make an international phone call anyway. The argument misses the point. It has never been possible to reliably block anything, even at customs. The persistent will always find a way around the censors. The censor's goal is achieved if it is difficult for *most* users to access the material.

The French approach may be used in other countries. Korea has reportedly ordered its Internet service providers to block access to Korean-language pornographic sites hosted overseas that do not restrict access with an age-verification process.^[31]

A major case regarding blocking access to the Internet is the dispute between Antigua and the United States over Internet gambling. In 2003, Antigua filed a formal complaint against United States with the World Trade Organization (WTO), arguing that the United States' restricting online gambling violated obligations that it had made in 1994 regarding international trade. The United States argued that it was blocking access to online gambling sites on moral grounds. In 2004, the WTO ruled in favor of tiny Antigua. The United States appealed and lost in 2005.^[32] On December 2007, after long debates and many delays, the WTO finally ruled that Antigua won compensation of US\$21 million per year from the United States. However, the United States continued to refuse to comply and at the time of writing, Antigua has threatened to abrogate all its intellectual property treaties with the United States and open itself to allow piracy of movies and music on the island.^[33]

ARGUMENTS AGAINST CENSORSHIP

Problems of Internet Censorship

Even with traditional media, censorship has never been 100% effective 100% of the time. With the Internet, it is even more difficult to censor.

The root of the problem for censors is that the Internet combines characteristics of the newspaper, telephone, the radio, the television, and the computer. Each of these inventions alone has contributed to an increase in the transmission and reception of information. Combined, they offer a surfeit of information for censors.

Second, the reach of the Internet ranges the spectrum from one-to-one (e-mail)—which is usually uncensored—to one-to-many (Web sites) and many-to-many (Usenet groups)—which tends to attract some form of censorship. No technology before has had such a combination of reach. E-mail is generally viewed in most countries as private communication, an “e” version of regular mail. But it is possible to conduct mass mailings and some discussion groups are conducted through such mailings. In short, e-mail, a private communication medium, has the potential to be a mass medium.

Theoretically, there is no reason that e-mail cannot be read and censored. It just takes a lot of work. Opening and reading e-mail, however, may well be the most effective means of turning users away and killing the growth of the Internet. In 1994, through a misunderstanding of a high-level official request, Internet accounts of an access provider in Singapore were scanned for .GIF files. Of 80,000 files scanned, five were found pornographic by Singapore standards and the users were warned. Although no non-GIF file was opened, users nevertheless were irate. Many expressed grave reservations about security and privacy on the system. In the end, the access provider had to assure its users that no such scanning will occur in the future.^[16]

Third, there is the problem of regulatory paradigm. By combining the traits of traditional communication media and blurring their boundaries, the Internet poses the question of who is to regulate the content and by what standards even domestically.

Should the Internet be treated as a postal service because it has e-mail? Or would the capabilities of Internet Relay Chat and voice-telephony make it a telecommunication service? Then does the presence of electronic newspapers make it a print medium? Or should the availability of radio and television stations make it a broadcast medium? Should its use of the computer mean that the computer model of regulations applies?

In practice, regulators bypass these questions by treating the Internet based on its functions. That is, a Web-based newspaper is likely to be treated as a newspaper, an online radio station as a radio station. It means that there is no single regulatory paradigm. Such an approach, however, is not sustainable in the long run because it magnifies the regulatory problem of convergence where different rules and standards apply to convergent products and services. For example, is a news Web site that combines a newspaper with television news to be treated as a newspaper or a television station?

The fourth problem in Internet censorship is that the computer culture celebrates maximum (and sometimes anarchistic) freedom, not censorship. The early Internet operated with a loose, informal consensus. It arose from universally accepted technical protocols for carrying on electronic conversation from remote locations and times, and it gave birth to common language, culture, and norms.

No matter how system administrators at individual sites may restrict access to objectionable materials, savvy users can overcome the hurdles. Sites that are banned in one country are quickly relocated in another. Sites that are blocked are bypassed through anonymizing proxies. Ways and means to bypass censorship are published online.^[34]

Fifth, the Internet highlights a major legal issue in global interconnectivity: which censorship standard applies? The issue extends beyond the classic “what is pornography” debate as first highlighted in a U.S. case where a bulletin board service (BBS) operator in California was convicted of delivering pornography to a resident in Tennessee.^[35]

The Internet offers a myriad of material on subjects such as drug culture, bomb-making, murder, and anti-Semitism. Material that is illegal in one country and punishable with a heavy sentence may be wholly legal in another part of the world.

Germany’s case of the Neo-Nazis frames the problem best. In January 1996, the German phone company Deutsche Telekom blocked users of its computer network from accessing the Web site of Ernst Zündel, a German-born activist living in Toronto, Canada, suspected of distributing Neo-Nazi and anti-Semitic material over the Internet.^[36] Given the history of Germany, such a response is perhaps understandable.

However, in the United States several prestigious universities offered to mirror Zündel’s site.^[36] Similarly, when Germany tried to block access to a magazine called *Radikal*, 47 other sites all over the world mirrored the *Radikal* site.^[37] Enforcement of this German law outside of Germany is practically impossible. Any attempt at censorship therefore also has to consider the international dimension.

Finally, the process of regulation tends to proceed piecemeal and almost always lags behind changes in technology. Censorship of any new medium today is most likely to come into play after the objectionable material has been sent. Until then, censors would not be aware of the possibility of circumvention or violation. In the interim, before the passage of any regulation, there is the gray area.

METHODS OF CENSORSHIP

Access Control

Negroponte has said that bits and bytes do not stop at borders.^[38] Authoritarian regimes, however, can stop them. A 2001 study of the Internet in China and Cuba illustrated this point: the Internet does not automatically disempower authoritarian governments.^[39] In Myanmar, modems, even those built into laptops, have to be licensed. Those who use unlicensed modems have been jailed.^[40]

Slightly less draconian is the use of centralized access, typically through some form of state control. A number of states in the Middle East—such as Syria, Iran, and Iraq—use this approach. The fear of being caught accessing unauthorized material is the deterrent. However, the limited means of access discourages competition, which inhibits the diffusion of the Net.^[41]

China regulates access in another way: by compelling Internet subscribers to register with the police.^[42] Those who use the cybercafes have to show some identification before being able to access the Net. Lest the idea appear too wild, a similar notion of registering users has been proposed by Robert Cailliau,^[43] the codeveloper of the World Wide Web with Tim Berners-Lee.

In Singapore, Internet access providers have to use proxy servers to block 100 “high-traffic” pornographic sites for home subscription plans.^[44] The process of having to look up the blacklist does slow down access a little.^[45] Such centralized controls have limited capabilities: at most, several hundred pornographic sites can be blocked in the face of hundreds of thousands others.

To block these hundreds of thousands of sites, companies have sprung up to offer regularly updated blacklists of pornographic sites. The names of these sites are then blocked from user access. Such a family-friendly Internet access plan is increasingly available throughout the world. However, because of the costs of installing and maintaining the list, subscribers have to pay more for such plans.

Passing Laws

A common misperception is that if there are no new rules for the Internet, it means the Internet is not regulated. This perception is misplaced because in the United States, Internet users have been convicted for violating pre-Internet state laws concerning pornography.^[14]

In South Korea, a government official was quoted in the 1990s as saying: “A South Korean who meets by chance a North Korean on Internet had better report to the police within seven days.”^[14] South Korean security police in the 1990s have tracked down users who, in online debates, expressed opinions that could “benefit the enemy.”^[14] Such actions are authorized by the National Security Law. According to a civil rights activist, Kim Young Sik, president of the South Korean Civil Union Against Censorship, users have had their access restricted because of comments that were deemed to be in violation of the National Security Laws.^[45]

How successfully existent laws can be applied to the Internet depends on how well an analogy can be drawn to the Internet. In Singapore, for example, Web sites of religious and political organizations, as well as online newspapers produced locally, have to be registered.^[46] Although the law appears novel, it is essentially an adaptation of existing media laws in Singapore.

As regulators understand the Internet better, they have attempted to pass legislation to regulate content. However, passing Internet-specific laws does not necessarily imply a censorial intent. In many countries, it is necessary to pass Internet-specific laws because the medium is new. For example, without Internet-specific laws recognizing electronic evidence, it would be impossible to conduct e-commerce.^[47]

That laws in the United States and France were struck down because they conflict with freedom of expression does not mean that it is not legally possible to censor the Internet. What it means is that legislators cannot simply rush the laws for political expedience. Initially, perhaps because the medium is so new, the laws appear not to have been well-thought out.

In the European Union, soon after publication of the EU paper on “Illegal and Harmful Content on the Internet,”^[48] Internet service providers were, for a time, fearful of possible legislation that would make them liable for content for which they had not originated. Since then, Internet-specific immunity provisions have been written in a range of countries—Germany, United States, Singapore, India, Bermuda, France, Australia—so that intermediaries who do not originate content would not be held liable.^[49] The immunity for intermediaries is an example where laws need not be restrictive of the Internet.

Using Technology

Laws, however, are blunt instruments for what is essentially a delicate task of picking and choosing content to be removed. Inevitably, the very technology that has enabled the spread of the information has been used to censor. However, the result has been mixed at best.

Probably the first program to censor the Internet was developed by medical researcher Richard DePew in 1993. Annoyed by anonymous messages on the Usenet groups he read, he developed a program he called Automated Retroactive Minimal Moderation (ARMM) to delete them. The program failed at first. Several versions later, when it succeeded, it affected the workings of other connected computers.^[50]

Many Usenet readers disagreed with DePew’s deletions because it deprived them of the messages. Since then, DePew has stopped using ARMM. Instead, he has developed a program called a bincancel-bot, which removes inappropriately placed binary files from Usenet groups. Such binary files tend to be large, usually contain either programs or images, and are often off-topic. This time, there was a more muted reaction.^[51]

A similar “cancelbot” was first used spam sent by law firm, Canter and Siegel, who in 1994 sent to more than 1000 Usenet groups off-topic advertisements hawking their legal services. A 25-year-old Norwegian programmer, Arnt Gulbrandsen, developed a cancelbot that hunted down and deleted messages sent by the firm.^[52] However,

there is room for abuse. In September 1996, a computer user in the United States sent an unauthorized cancelbot to remove 25,000 messages from the Usenet.^[53]

As might be expected, there are software circumvention tools to defeat censorship; they may be successful in varying degree, depending inversely on how earnest the censors are. It is a cat-and-mouse game. For example, China's censorship has become more sophisticated. In 2002, on a visit to Shanghai, the author saw that Google's search results were blocked for the actual site but not for the cached version. So it was easy to bypass the censorship. But a later year, access through the cache was also blocked.

Anonymising programs and proxies make it difficult for the censor to trace the user and thereby may be able to defeat a block. Tor and Psiphon software allow users to access the Internet through a computer with uncensored access. As might also be expected, there are sites giving advice on how to beat the censors.

Filtering^[54]

Of all the technological means to censor the Internet, the most widespread is filtering by the end-user. The goal of filtering is to empower parents to block undesirable content to children, the only group for which censorship is internationally accepted. One category of filtering software resides in the user's computer. Much in the same way as antivirus software, such filtering programs require regular updates for sites to be added. Another category of filters resides in the server and is a service provided by the Internet service provider; users subscribe to the service, usually on a monthly basis. Filtering software programs have been endorsed, at one time or another, by industry and governments in Europe, Australia, and the United States.

Such programs have improved in sophistication. Initially, some of the software blocked off sites merely for having words such as "breast" on its pages. There were concerns by civil libertarians that this meant blocking educational or medical sites. Today's filtering programs are more context sensitive. Nevertheless, they still suffer from two inherent limitations of such programs. First, filters have to balance the need to be accurate with the comprehensiveness of the filter. The more comprehensive the filter (the more offensive words it recognizes), the less accurate it will be in parsing context. The second limitation is that the filter software needs to be updated frequently.

TRENDS

A few years ago, it was easier to discern the trends: overall, the Internet would make countries freer.^[55] After the September 11, 2001 attack, however, security has become

a more important part of network policy. The freewheeling Internet has become less freewheeling.

Governments often point to a historical or cultural basis for censorship. In the classic case, Germany has had its memory-searing record of anti-Semitism. Singapore had a history of race riots in mid-1960s. South Korea has its fear of the North Korean invasion. And so the bias toward security and censorship, instead of openness, has a basis in historical events.

Some form of censorship, perhaps better phrased as content regulation, of the Internet is here to stay. The question is the degree and the form of censorship. In some ways, censorship of the Internet is more severe than censorship of traditional media. In the digital world, one either receives the content or not at all; a garbled message is usually unreadable. In the analog world, one may receive the content partially. A garbled message may be partially readable; a printed copy may be smudged or covered over but parts may be readable. Also, online censorship is often through a blocking mechanism, which is prior restraint. Legal doctrine views this as a more severe form of censorship than restriction after publication.

There are several areas where censorship is on the rise. A developing area of censorship is copyright. The early use of copyright was indeed for censorship. There is very little debate on this issue as rights are being extended by rights-holders, at the expense of society at large.^[56]

U.S. companies such as Yahoo and Google face the question of the extent to which they should respect the laws of a foreign land when that law clashes with a fundamental value such as free expression. In Yahoo's case, the company has swung from ignoring the French government to being wholly compliant to the Chinese government's request for the name of a journalist, who was subsequently sentenced to 10 years imprisonment for disseminating "state secrets." Ironically, Yahoo was not legally bound to do so.^[57] The European Union has issued a declaration urging companies that do business in repressive countries to develop a code of conduct to "put limits on the activities of companies in repressive countries."^[58] Yahoo, Google, Microsoft, and a few others did attempt such a code but at Yahoo, it was rejected by the shareholders.^[59] Reporters Without Borders in 2005 got 35 investment firms to sign a "Joint investor statement on freedom of expression and the Internet" and to "monitor the activities of Internet sector companies in repressive countries."^[60] It is however, difficult to see how such a code would be implemented because it would mean disobeying the laws of a land that the business operates in censorship and trade.

CONCLUSION

Censorship tends to be more tolerated in times of crisis and war. At the time of writing, the war on terrorism in

Iraq, Afghanistan, and around the world was still raging. A greater degree of censorship and other retrenchment of civil liberties may therefore be expected. Temporarily, at least, the freedom and anarchy that the Internet vanguard had hoped for is likely to be curtailed from the West.

The future of freedom on the Net, however, is bright. Freedom House's study of Net freedom concludes that the large number of users alone will make it hard for governments to censor, and that thereby creates more space for public debate. Free speech has either won or will win any battle censors may put up over the Internet.

As the Internet has developed, it is also clear where the boundaries are for censorship. The one area that virtually all countries agree to censor is materials that go to the young. The United States has gone so far as to impose laws, such as the Children Online Privacy Protection Act, that have closed down Web sites. Other areas that developed countries are prepared to see regulated are child pornography and representations to consumers that spill over to become consumer fraud.

Apart from these areas, censorship laws become murky and harder to defend. Many people accept that countries do have a right to their own cultural identity. And certainly history plays a part. But not every one agrees how that culture and history should be treated. Hence the debate over censorship will continue. Especially on the Internet.

Center for Research Libraries

Mary I. Wilke

Center for Research Libraries, Chicago, Illinois, U.S.A.

Abstract

The Center for Research Libraries fosters and advances scholarly inquiry through cost-effective, cooperative programs that provide reliable access through traditional and electronic means to unique and unusual collections of library materials in all appropriate formats, international in scope, and comprehensive in disciplines.

INTRODUCTION

The Center for Research Libraries (CRL) is an international consortium of university, college, and independent research libraries. The CRL supports original research and inspired teaching in the humanities, sciences, and social sciences by preserving and making available to scholars a wealth of rare and uncommon primary source materials from all world regions.

CRL

History

The CRL was founded in 1949 as the Midwest Interlibrary Center by ten Midwestern research universities. The founding institutions were the University of Chicago, the Illinois Institute of Technology, the University of Illinois, the State University of Iowa, Indiana University, the University of Kansas, Michigan State College, the University of Minnesota, Northwestern University, and Purdue University. It arose following a decade of study and planning for a regional cooperative deposit library. As originally conceived, the CRL was to serve four programmatic purposes: cooperative storage of little-used materials, cooperative acquisitions, coordination of collecting policies, and centralized cataloging. Of these four functions, centralized cataloging and coordination of collecting policies proved unworkable at that time. The founding planners pursued, rather, the creation of a consortium whose role would be to develop and maintain a corpus of scholarly research materials, assembled cooperatively through deposits and purchases and to make those materials available to consortium members.

Construction of the storage and processing facility was completed in 1951, and the CRL opened in that year. In the ensuing half century, the consortium has grown to include more than 210 research universities and libraries

from North America. In 2005, the University of Hong Kong became the CRL's first global member. Since then, the Max Planck Institute for Human Development in Germany and Nalanda University in India have joined as global members. The CRL now maintains a centralized collection facility and a corpus of research materials consisting of more than five million volumes and microform volume equivalents.

The need among academic libraries for cooperative solutions to acquisition and storage problems in the mid-twentieth century became, if anything, more pressing with the passage of time. In his article about the CRL in the first edition of the *Encyclopedia of Library and Information Science*, Ray Boylan stated that as "knowledge (and the publications containing it) has grown, researchers have had to become more specialized in order to master it."^[1] Despite such adaptive behavior on the part of scholars, individual academic libraries were scarcely able to purchase, catalog, store, preserve, and make available all of the materials necessary to meet the specialized research needs of faculty and students. In the intervening years, the growth of scholarly resources has only accelerated. At the same time, the scope of scholarly inquiry has been enlarged as well, through the introduction of new disciplines and fields of study. The late-twentieth-century revolution in digital technology also expanded the array of media through which scholarly communications are transacted, thus raising the prospective costs of comprehensive collecting in those disciplines to higher levels while competing with the need to provide electronic access to resources. As the need has grown, so have the services, collections, and programs the CRL offers.

Global Resources Collaborations

To address the changing realities of humanities and social science research, the CRL has formed strategic partnerships with other organizations whose goals align with the CRL's mission. Through these partnerships, the CRL

brings new expertise and resources to bear on its efforts to digitize, preserve, and provide access to published materials in four major domains.

Partnerships

Global Resources Agriculture Partnership—Project Ceres: The CRL works with the U.S. Agricultural Information Network and the Agriculture Network Information Center to support the ongoing preservation and digitization of historical collections in the field of agriculture. The CRL provides funding to libraries to digitize and commit to preserving print materials essential to the study of the history and economics of agriculture.

Global Resources Law Partnership: The CRL works with the Law Library Microform Consortium (LLMC) to expand access to legal and governmental primary source documents serving the research interests of the CRL's diverse library community. The CRL and LLMC identify, preserve, and provide digital access to important at-risk primary source documents in law and government from the United States and other national jurisdictions.

Global Resources Partnership in Science, Technology, and Engineering: In 2012, the CRL and the Linda Hall Library (LHL) of Science, Engineering, and Technology formed a strategic partnership to preserve, further develop, and provide access to historical research collections in the fields of science, technology, and engineering. The partnership builds upon the rich holdings of print serials in those fields assembled by the two institutions during the past six decades. The combined holdings of the two institutions constitute a premier library of global science. The CRL and LHL are pooling resources to promote the visibility of these collections worldwide, making them available electronically and through traditional interlibrary loan (ILL) and document delivery to researchers through the CRL libraries.

News: Access to news in its many forms requires coordination and participation of a variety of stakeholders. As one of the foremost news collections in North America and the world, the CRL works to systematically identify critical collections; establish consensus on preservation, archiving, and digitization needs; and negotiate licenses and partnerships to obtain access to materials available electronically. The CRL's partnership with Readex on the World Newspaper Archive supports the library community's efforts to preserve and provide persistent electronic access to historical newspapers from around the globe. Through its work with the International Coalition on Newspapers (ICON), the CRL partners with major news repositories around the world to preserve and improve access to historical news collections. ICON places increasing emphasis on assessment of sustainable digital news repositories, and the ICON database of newspapers is the most comprehensive source of information on digitized newspapers in trustworthy repositories.

Additionally, the CRL represents the interests of its members to obtain favorable terms of access to historical (digitized) and current (born-digital) news sources. The CRL establishes relationships with media organizations (such as the New York Times), commercial providers, and academic partners to ensure the persistence and accessibility of these resources.

Global Resources Programs

AFRINUL: The Cooperative African Newspapers Project seeks to enhance the utilization of newspapers as a source of information about Africa. The project has developed the African Newspapers Union List (AFRINUL), a centralized electronic database of holdings information for newspapers (all formats and all languages) published in sub-Saharan Africa.

CAMP: The Cooperative Africana Materials Project (CAMP) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous Africana research materials for its members. CAMP emphasizes original preservation of newspapers, journals, government publications, archives, and the personal papers of scholars and government leaders.

CIFNAL: Collaborative Initiative for French Language Collections (CIFNAL), the Collaborative Initiative for French Language Collections, was founded in 2006 to promote and facilitate the cooperative exchange of ideas and resources between Francophone and North American research libraries. CIFNAL seeks to improve access to French and French-language resources through licensing, digitization, and institutional connections.

GNARP: The German–North American Resources Partnership (GNARP) supports the acquisition, sharing, and use of German-language materials among North American libraries and the fostering of closer collaboration with German research libraries.

HRADP: The Human Rights Archives and Documentation Program (HRADP) facilitates efforts by institutions to identify, preserve, and provide access to human rights–related archives and documentation by collecting and sharing information about the nature and status of at-risk materials and providing other technical, communications, and financial support for preserving and maintaining those materials.

ICON: ICON is a multi-institutional effort to promote the accessibility and preservation of international newspaper collections by gathering and providing data on physical and digital collections of newspapers from all world regions. The program supports the ICON Database of International Newspapers and conducts assessments of major newspaper digitization initiatives.

LAMP: LAMP (formerly known as the Latin American Microform Project) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous Latin American research materials

for its members. LAMP emphasizes original preservation, either through microfilming or digitization, of newspapers, journals, archives, and ephemeral material from Latin America and the Caribbean.

LARRP: The Latin Americanist Research Resources Project (LARRP) is a cooperative initiative that seeks to improve access to the array of research resources published in Latin America. LARRP supports collaborative projects that increase free and open access to information in support of learning and scholarship in Latin American studies and cultivates relationships within the academic library community.

MEMP: The Middle East Materials Project (MEMP) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous research materials pertaining to the field of Middle Eastern studies for its members. MEMP emphasizes original preservation, either through microfilming or digitization, of newspapers, pamphlets, and ephemeral material from or about the Middle East and the Arab world.

PAN: The CRL sponsors the Print Archive Network Forum (PAN), a biannual meeting held in conjunction with ALA conferences, to share information, expertise, and best practices about strategic management of print archive programs. PAN invites libraries and consortia of all sizes to participate.

SAMP: The South Asia Materials Project (SAMP) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous research materials in South Asian studies for its members. SAMP emphasizes original preservation, either through microfilming or digitization, of newspapers, journals, official publications, monographs, and ephemera in all languages of South Asia.

SEAM: The Southeast Asia Materials Project (SEAM) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous research materials in Southeast Asian studies for its members. SEAM emphasizes original preservation, either through microfilming or digitization, of newspapers, archives, manuscripts, journals, and ephemera relating to all countries of Southeast Asia.

SEEMP: The Slavic and East European Materials Project (SEEMP) acquires, preserves, and maintains microform and digital collections of unique, rare, and bulky or voluminous research materials pertaining to the field of Slavic and East European studies for its members. SEEMP emphasizes original preservation, either through microfilming or digitization, of newspapers, journals, books, archives, pamphlets, and other relevant materials from the region.

TRAIL: Technical Report Archive and Image Library (TRAIL) works to ensure preservation, discoverability, and persistent open access to government technical publications regardless of form or format. TRAIL identifies, acquires, catalogs, digitizes, and provides persistent and free access to historical collections of federally funded

technical research reports held by research libraries and other organizations.

The Collection

The CRL holds more than five million newspapers, journals, dissertations, archives, government publications, and other traditional and digital resources for research and teaching. Holdings include such diverse materials as 800,000 doctoral dissertations from outside the United States and Canada (including those of Albert Einstein, Dag Hammarskjöld, and other Nobel Laureates), some of the earliest African-American newspapers, and several human rights-related archives. Emphasis is on materials produced outside the United States, and the CRL has special strength in publications and archives from developing nations.

Resource Sharing

The CRL is committed to fast, accurate delivery of materials and digital content for faculty and student research. ILL provides a mechanism for access to CRL materials by members. One of the most important CRL ILL features is unlimited access to important research materials with extended loan periods: patrons from member libraries can make an unlimited number of requests, request any amount of material to be sent, and are allowed to use the CRL materials for as long as necessary. (The CRL will recall an item only if another patron from a member library requests the material.) The lengthy loan period is possible because the CRL collects material that is rarely used at single institutions. On-demand digitization of fragile and rare material, if possible after assessing condition, is also a service the CRL provides. The CRL staff has worked to improve discoverability of its tangible and digital resources by creating cross-links to the CRL OPAC and web-based collection guides from various open-access web resources developed by the CRL and its affiliates.

Cooperative Collection Development

Since its earliest days, cooperative collection development was accomplished in two ways: through the CRL's deposit service and through the CRL's purchase programs. Initially, many of the CRL's original members deposited material that was rarely used in their own libraries (Fig. 1). The depositing library gained shelf space in their own stacks for the acquisition of new materials. These deposits formed the core of many of the CRL's collections. The deposit program remains an important service for both the individual member library and for the larger community as the CRL continues to receive titles for its JSTOR print archives (JSTOR was the Andrew W. Mellon

Foundation's acronym for the "Journal Storage" Project). The CRL/JSTOR Print Archive Project provides assurance to the CRL members and to the library community that paper copy of all JSTOR titles will be available as an archive. More information about the CRL/JSTOR Print Archive Project is available at <https://www.crl.edu/archiving-preservation/print-archives/crl-administered/jstor>.

The second part of the CRL's cooperative collection program is its purchase programs. Material is purchased in four ways: subscriptions, demand purchases, purchase proposals, and shared purchases. From the CRL's inception, certain classes of materials had been identified as material the CRL should collect. Selected titles in these classes are acquired through subscriptions. In fact, when the CRL opened for business in 1951, it began with entering subscriptions to 40 newspapers. Along with the newspaper subscriptions, the CRL maintains subscriptions to

various rarely held serial titles, such as the *Asian Journal of Chemistry*.

The Demand Purchase Program works with the classes of materials the CRL specifically collects: newspapers, foreign doctoral dissertations, and archival records. Each year, a percentage of the collection budget is set aside to purchase-on-demand materials in these classes if a patron from a member library so requests and the CRL does not presently own them. One example concerned a researcher studying the Berlin Airlift. Relevant material from Public Record Office files had recently been micropublished. The researcher was able to request the CRL to purchase this archival material using its Demand Purchase Program. The patron's library did not have to spend money and time on purchasing, cataloging, and storing the material. Other member libraries also benefited from the CRL's

Fig. 1 Cover of *Locomotive Engineers Journal*, July 1922, Vol. 52.

acquisitions of this material, as they did not need to purchase the material for their own library.

A portion of each year's budget is set aside for the Purchase Proposal Program. Each year, representatives from member libraries propose titles for purchase through this program. If the proposals meet the specified criteria, the item is balloted. The criteria can be found at <https://www.crl.edu/collections/cooperative-collection-building/purchase-proposal-program>. Member libraries then rank items on the ballot and the CRL purchases as many of the approved titles as possible with the year's available pool of money. Many of the major microform sets the CRL owns were acquired through this program. Recent acquisitions of material through this program include "Church Missionary Society Archive. Section III: Central Records, Parts 12–22", "La Dépêche algérienne: journal politique quotidien (1885–1943)", and "Qing gong nei wu fu zou xiao dang."

How to Use CRL

As mentioned earlier, the use of the CRL's collections by patrons at its member institutions is free and unrestricted. As the CRL's collections are rarely held and used at any single institution, a researcher can often have the luxury of loan periods lasting years. The use of the CRL's collections, for those not affiliated with a CRL member institution, is provided on a cost recovery basis and subject to certain limitations. For more information, read the nonmember loan policies found at <https://www.crl.edu/services/borrowing/non-member-lending>.

The CRL's online public access catalog (<http://catalog.crl.edu/>) contains more than 1,300,000 records. However, many of the materials held by the CRL are uncataloged. Presently, the CRL is working to provide more access to these collections and more information can be found in the section "Other Collections" here: <https://www.crl.edu/collections/crl-collecting-areas>.

CONCLUSION

The CRL was founded at a time when individual university libraries realized they could not be self-sufficient. Time has shown that cooperative collection development and resource sharing remains essential for academic libraries. The CRL aims to realize a shared network of traditional and digital resources for scholarly research and teaching and to develop and manage these resources strategically for the benefit of the academic and independent research libraries community.

Charleston Conference

Katina Strauch

Addlestone Library, College of Charleston, Charleston, South Carolina, U.S.A.

Abstract

This entry covers the history, founding, evolution, structure, values, and future directions of the Charleston Conference held annually in Charleston, South Carolina.

HISTORY AND FOUNDING

The Charleston Conference was begun in 1980 by Katina Strauch who was the then newly hired Head of Acquisitions at the College of Charleston's Robert S. Small Library. At that time the library had a small materials budget (\$150,000) for all material acquisitions. The library also had no travel budget and little knowledge of acquisitions processing. However, the Library staff was a young, energetic, and innovative group. The Head of Special Collections at the time, Dr. Ralph Melnick, was planning an Antiquarian Book Fair, and the Head of Reference, Cerise Oberman-Soroka, was already running a highly successful conference for reference librarians on approaches to bibliographic instruction. The College also had hired a new continuing education director, Sue Sommer. Sue, Ralph, and Cerise encouraged Katina to start a conference connected with the Antiquarian Book Fair focused on acquisition of rare and out of print materials. Accordingly, the first Charleston Conference's speakers included, among others, Jake Chernofsky, Editor of *AB Bookman's Weekly for the specialist book world*, Bob Barrows from Arno Press, and Paul Koda, Rare Books Librarian, University of North Carolina (UNC)-Chapel Hill. There were approximately 25 attendees including Mike Markwith (Blackwell's), Corrie Marsh (Georgetown), John Ryland (Hampden-Sydney College), Bill Schenck (UNC-Chapel Hill), and Tom Leonhardt (Duke University). Several of the papers from that first meeting were published by Jake Chernofsky in *AB Bookman's Weekly*.

After the first Conference, word spread. Since there were no other conferences like this for acquisitions personnel, there was no need for organized publicity, just word of mouth. So a grassroots gathering of a handful of acquisitions librarians has grown over the ensuing three decades to over 1500 attendees in 2012. The timeline as created for the Conference's 25th anniversary is included at the end of this essay.

GUIDING TENETS AND EVOLUTION OVER TIME

Originally held in the spring and spanning two days, the Conference was moved to the first or second week of November because academic acquisitions librarians normally are too consumed by their local institution's budgetary issues in late spring. Based on attendees' recommendations, it was also lengthened a half day into Saturday, which allowed attendees to drink in the appeal of historic Charleston as a venue and to offer additional sessions to an audience of broader professional scope.

After the Conference was several years old and its attendance was growing, Katina felt the need to initiate more frequent communication with past attendees. Accordingly, and with the help of Steve Johnson, Head of Acquisitions at Clemson University who had his own beer lover's newsletter and helped with the layout, Katina and her husband Bruce launched *Against the Grain: Linking Publishers, Vendors, and Librarians* in March 1989. Originally conceived as a four-page mimeographed handout for Conference attendees only, *ATG* grew quickly.

The first issue was 10 pages long instead of four, and *ATG* issues now comprise a minimum of 88 pages. The first issues of *ATG* were distributed by Ballen Booksellers International and Alfred Jaeger, Inc. with help from Ambassador Books, Inc. Ads were not initially intended for the publication, but *Against the Grain* began to get requests for ad space. Edna Laughrey, former Head of Acquisitions at the University of Michigan, volunteered and became *ATG*'s first ads manager. Thus, Katina began to involve willing Conference attendees in increasing the reach of the Conference to the library and publishing world. Word of the Conference continued to spread, and attendance continued to grow.

The program for the first decade of Charleston Conferences was a series of consecutive plenary talks by a handful of speakers. However, in the 1990s, as the online, networked world began to expand, topics were too diverse to fit into a series of plenary talks given over only two and one-half days. Traditional lines of demarcation between

the operations inside libraries have blurred and continue to blur, and the Charleston Conference has been able to stay not only current but be on the cutting edge of factors influencing change in information's allied professions.

The Conference is an organic, living organization. As such, Conference organizers began to plan concurrent presentation sessions to complement the generally broader-scope plenary presentations. These concurrent sessions tended to be subject or process focused and allowed more attendees to present their research findings to the professional information community. The 2015 Charleston Conference included over 300 such concurrent sessions.

Over time the original focus of the Conference on acquisitions applications in academic libraries has broadened to encompass a full range of ideas, problems, and opportunities faced by scholarly publishers, vendors, and libraries and the advancement, sharing, and preservation of knowledge. Topics such as copyright and compliance, standards, communication, digital rights, networking, technology advances, budgets, and archiving are germane to everyone in the information profession.

When Katina began the Conference, she had two caveats. First, she did not want concurrent sessions; she wanted everyone to hear the same paper at the same time and react to its content as a community. Second, she did not want exhibits as she felt the Conference should be about ideas and not become a commercial venue. Also, as a newly minted acquisitions librarian from an unknown academic library, she wanted to create a venue that wasn't just for the "big guys" and already-well-known librarians. She didn't want to exclude them, of course, but she wanted to be mindful of the little, insignificant guys, many coming from small academic institutions. The Conference has held true to the original attendee-inclusive objectives for thirty-six years.

Although as concurrent sessions became a necessity given the explosion of the virtual world and the growth of attendance, the Charleston Conference still gives opportunities for presentations, open questions, friendly repartee, and continued discussion to players from all types of academic libraries, interested public and special libraries, scholarly publishers, vendors and aggregators, consultants, students, etc. Unknown participants are frequently given special consideration when they are identified. A third caveat—Katina wanted to preserve informality, giving the opportunity for give and take during plenary. Microphones are opened to the audience after each plenary presentation, and anyone wishing to comment or question is encouraged to do so. The only requirement to speak is to first identify oneself.

Regarding the introduction of commercial exhibits, in 1999, after attending conferences with exhibits of all sorts of products, the organizers decided to trial a focused Vendor Showcase. This allowed companies with products of direct application and interest to collection developers, acquisitions librarians, serials librarians, digital services librarians, etc. to showcase their products for librarians to

see firsthand, unencumbered by multiple products less applicable to the relevant information professional in attendance. The now successful Vendor Showcase is held prior to the main conference on Wednesday for an eight-hour period and does not conflict with programming on Thursday, Friday, and Saturday. The exhibits are kept simple; tables may be shared by more than one related vendor/publisher. The physical structure and short duration for the Vendor Showcase attains the informal feeling so characteristic of Charleston Conferences overall. Vendors do not have to staff exhibit booths during Conference presentations of interest to them. They are encouraged to send their most knowledgeable representatives to answer questions from Conference attendees and to interact openly in other sessions and social activities. A smorgasbord of refreshments set up in the middle of the Vendor Showcase area also adds to its pleasant and informal atmosphere.

ORGANIZATIONAL ISSUES AND DETAILS

As previously noted, a grassroots gathering of a handful of acquisitions librarians in 1980 grew to 1800 in 2015 and includes a mix of publishers, vendors, aggregators, consultants, students, and librarians. Spread over two and one-half days in early November—late Wednesday afternoon through mid-afternoon Saturday—broad, often controversial, topics of interest to the world of information professionals are explored in plenary sessions, which are interspersed with multiple concurrent "breakout" focused sessions exploring the practical, the novel, or the clever application to instruction and research. Speakers are drawn not only from the information professions of publishing, academic/public/research/government librarianship, vendors of information tools, and technology gurus but from the corporate world of the broader service industry sector, such as Google or Amazon. Prominent speakers, known for both their professional acumen and their presentation skills, are solicited, and expert panels providing opposing or complementary viewpoints are convened and are deftly moderated. A multisection, printed program offers not only the daily program schedule and a précis of each presentation but also the bios of all presenters and a list of those attendees who have preregistered along with their contact information.

The program itself is a feat of organization and information. The program is produced in hardcopy and in digital form available via the Conference website. When recently surveyed, attendees continue to want a printed program in addition to the online. Attendees can manage their own online Conference calendar. The Conference online program serves as a retrospective repository of sorts where presenters may add their slides postconference in addition to the abstracts of all presentations already available prior to the Conference. Recordings of all plenary sessions (when permitted by speakers) are made available free of charge on the Conference website as well.

Cognizant of travel budgets across academic libraries, online registration begins in early June before the end of most institutions' fiscal year. "Early bird" registration generally closes in early September, and regular registration generally is open through mid-October. On-site registration is possible but is not encouraged. The Conference secures blocks of rooms in several hotels—mostly those close to Marion Square in downtown Charleston. Shuttle buses are available between Conference hotels and venues on a limited schedule. The Charleston Area Convention and Visitors Bureau assists planners with hotel and restaurant information, and vendors can seek their assistance in planning ancillary entertainment.

The Francis Marion Hotel has served as the Conference's anchor hotel since the College of Charleston repurposed its adjoining Lightsey Center in 2001 where the Conference had been based for several years. Prior to the Lightsey Center, the Charleston Conference was held in several College of Charleston venues depending on availability and space required—a student commons room on campus, in the Education Center, and in the Sottile Theatre. Since relocating to the Francis Marion Hotel, which is too small to accommodate the entire Conference, the Conference has used several hotels and College of Charleston buildings in addition to the Francis Marion—the historic Embassy Suites hotel in downtown Charleston (the site of the old Citadel), the downtown Hampton Inn, the Marlene and Nathan Addlestone Library of the College of Charleston, the School of Sciences and Mathematics Building of the College of Charleston, and most recently the Marriott Courtyard (once a Holiday Inn). The Gaillard Center in downtown Charleston was renovated in 2015 and holds 1800 attendees. There are several additional hotels in the works in downtown Charleston, so the Conference planners are optimistic that downtown Charleston will continue to be a viable location for the Charleston Conferences.

The fact that the Charleston Conference is *not* sponsored by a professional association, such as ALA or AHA, contributes to its uniqueness. That no professional or corporate entity drives its focus gives Conference organizers the freedom to expand to where the action is, to predict where it will be, and nimbly go there first. Program design is in the hands of a small, unpaid leadership group providing continuity and structure. This contrasts positively against the design of programs for many professional association conferences where volunteer organizers come and go, and topics may be planned years in advance at a time when they are relevant, but relevance may have changed. Charleston Conference planners are able to put a program together with a shorter lead time; thus the programs offer immediate appeal and current relevance.

Regarding the Conference structure, seasoned attendees know what to expect of the day and when—lending calm to an otherwise frenetic schedule of presentations and associated activities. For those new to the Conference, a few "old-timers" serve as mentors to newbies by answering

their questions emailed prior to the Conference and are also available for additional guidance during the Conference, staffing an information table near the registration area. The use of mentors was brokered by Pam Censer, then at the University of Florida, and Susan Campbell of York College, who suggested it. The mentors welcome first timers and orient them as needed. Mentors also serve a "concierge" function for all attendees by interpreting local maps, giving directions, suggesting restaurants, and advising on transportation choices. Being available for immediate problem-solving assistance adds to their overall usefulness.

THE CONFERENCE PROGRAM

Each year's Conference is organized around a catchy theme, which drives the content of the plenary sessions and many of the concurrent sessions.

Included here is a list of all of the conference themes:

- 2016: Roll With the Times or the Times Roll Over You
- 2015: Where Do We Go From Here
- 2014: The Importance of Being Earnest
- 2013: Too Much is Not Enough (tentative)
- 2012: Accentuate the Positive
- 2011: Something's Gotta Give!
- 2010: Anything Goes
- 2009: Necessity is the Mother of Invention
- 2008: The Best of Times, The Worst of Times
- 2007: What Tangled Webs We Weave
- 2006: Unintended Consequences
- 2005: Things Are Seldom What They Seem
- 2004: All the World's A Serial
- 2003: Games People Play
- 2002: Two Faces Have I: One For Books and One for Bytes
- 2001: The Trends They Are A'Changing
- 2000: Is Bigger Better?
- 1999: And the Beat Goes On
- 1998: We Want More For Less
- 1997: Learning From Our Mistakes
- 1996: Money Talks
- 1995: Still Crazy After All These Words
- 1994: The Savage Marketplace
- 1993: Bubble, Bubble Toil and Trouble
- 1992: The Medium is the Message
- 1991: And I Am Right, And You Are Right, Too-Loo-Ra-Lay
- 1990: The Pure and Simple Truth (each session of this conference was prefaced with a quotation from Oscar Wilde)
- 1989: Remembrance of Things Past
- 1988: Questioning Assumptions
- 1987: Plus Ça Change
- 1986: External Influences on Acquisitions and Collection Development

- 1985: More Than You Ever Wanted to Know About Finance
- 1984: Old Problems, New Solutions
- 1983: Collection Development in the 1980s
- 1982: Charleston Conference did not take place. (Katina's daughter Ileana was born.)
- 1980, 1981: no overlying themes yet

Invited speakers deliver plenary presentations in the Carolina Ballroom of the Francis Marion Hotel. These approximately 45-minute presentations are simultaneously transmitted for viewing to large audiences gathered in several other ballrooms and large meeting rooms across the Conference venues. Each venue has at least one moderator who interacts via microphone with a counterpart in the Carolina Ballroom allowing those remote from the physical speaker to feel intimately involved in “the action.” Courtesy reigns in the Francis Marion ballroom even though contrarian views are encouraged. In 2015, plenary sessions were held in the Performance Hall of the Gaillard Center, which meant that all attendees were together in one venue.

Each year brings presentations of current interest, yet annual reprises of certain themes engender great audience anticipation. Recent favorites have been a panel discussion on recent—or anticipated—legislation and current court cases that affect the information landscape and a point-counterpoint debate on the future of the information industry. Speakers chosen as panelists speak to the multiple facets of a hot topic, recently the advance in technology and user acceptance of e-books. Individual plenary presentations may be delivered by prominent information professionals or by individuals prominent in advancing fields that impact the information professions.

Concurrent, smaller-audience, breakout sessions are more loosely organized, but several thematic tracks are offered for those interested in zeroing in on one facet of the information spectrum. Tracks such as budget/fundraising/allocation formulae, end users/use statistics/usability studies, management, and technology offer broadly targeted presentations. Individuals seeking to present choose the track where they feel their presentation would best fit, and Conference program organizers select from them to develop a balanced program. Location of the breakout session rooms across multiple venues is done differently from other conferences where a specialized group may hear presentations in the same room or two for the duration of the conference.

Theme tracks are less important in room choice than the size of the audience anticipated to attend. Room sizes at the several Conference venues vary widely and accommodate from 15 to 800.

The Charleston Conference is a dynamic community. Organizers welcome suggestions and ideas for innovations. Fast Tech Talks give companies a chance to showcase a product or service. Innovation Sessions allow participants to discuss or brainstorm new approaches. Poster Sessions give presenters the opportunity to display

information regarding their department or library. Preconferences are designed to delve deeply into a subject when there is insufficient time during a plenary or concurrent session and the topic is deemed by the organizers to be important. Juried Product Development Forums allow companies to discuss possible future products, ideas, or innovations with a small group of interested librarians. Dine-Arounds on Friday nights give attendees an opportunity to meet each other and try out the culinary fare in a nearby restaurant. Each of these program innovations was suggested by conference attendees or members of the Charleston Conference planning group.

Concurrent presentations at midday, termed “Lively Lunches,” allow attendees not to break their trend of concentration but to eat lunch in the meeting rooms during lunch-time presentations. With so many restaurants offering takeout in the immediate vicinity of Charleston's Marion Square, the Lively Lunches allow attendees to select their own fare with only a 30-minute recess. Over the past several years with more restaurant choices in the vicinity, more time has been allowed for attendees to get lunch and return to the sessions.

Breakout and Lively Lunch program choices are so varied that attendees must make their choices in advance. The sessions are kept small, and the number of concurrent sessions/Lively Lunches offered increases with the increasing number of Conference attendees. Questions are always encouraged in all sessions; microphones are also provided there as necessary. Members of the audience are encouraged to chime in with questions or to add their own experience/opinion. Often there is much give-and-take between presenter and audience to the benefit of all assembled. Most breakout sessions attract at least seven attendees, and some require extra chairs for forty or more. Sessions expected to draw the biggest crowd are scheduled in the larger conference rooms in the Francis Marion or the Marriott Courtyard—hotels located around the edge of Marion Square. Some sessions are held in the College of Charleston's Addlestone Library, which offers an opportunity to explore that lovely building opened in January 2005. Sessions have also been held in the College's School of Sciences and Mathematics Building across the street from Addlestone. Prior to 2001, the College of Charleston's Lightsey Center served as a venue. In 2015, many breakout rooms were made available at the opening of the Gaillard Center four blocks away.

The Gala Reception buffet on Thursday evening is included in the registration fee and has been held in various locations about town, for example, the South Carolina Aquarium, the Old Exchange & Provost Dungeon, the College of Charleston School of Sciences and Mathematics Courtyard, the William Blacklock House, and Rivers Green of the College of Charleston. A particularly memorable event was an oyster roast held at the city's Visitor Center. The city's stamp is continually intertwined into the culture of the Conference. For those attendees whose employers do not reimburse meals, this Conference does not send them back home hungry!

Late Wednesday afternoon's Juried Product Development Forum presentations, for which a limited number of noncorporate conference attendees may register in advance, allow vendors to test the market for a product or procedure in the development stage before introducing it to the market. Vendor submissions are reviewed by an anonymous panel, and the successful applicants must demonstrate that their product/process has been developed to the point where it can be judged; they cannot simply look to bounce an idea off the participant group. As a result, an interested and knowledgeable audience provides feedback in time for a revision, improvement, or extension.

The Conference's commitment to a responsive culture is demonstrated by a postconference Rump Session held on Saturday afternoon to immediately review the past days' events. All attendees are invited, and thinking begins for the next year's Conference. Conference critiques are requested from all registrants and are analyzed for their suggestions. Thus, the planning cycle begins anew.

CONFERENCE ADMINISTRATION

The Charleston Conference has several important working groups. The local arrangements group handles registrations, hotel logistics, communicates with registrants, and the like. This working group consists of three key people who keep everything in order. The Charleston Conference content planning group selects keynote speakers and concurrent session presentations. This group consists of librarians, publishers, and vendors from many areas. Members of the planning group stay involved as long as they are able. Additional members of the planning group are added every year. The Conference planners like continuity.

There is a primary leader of the Conference planning group. The first primary contact was Judy Webster, Head of Acquisitions at the University of Tennessee, who unfortunately passed away too early. The next primary contact was Rosann Bazirjian who was at Penn State University at the time and is now Dean of Libraries at UNC-Greensboro. Rosann has recently retired. The current primary program contact is Beth Bernhardt also at UNC-Greensboro.

Several key individuals contribute to the overall success of the Charleston Conference. Leah Hinds is the primary contact for the Conference overall. Leah oversees registration and is the Associate Director of the Charleston Conference. Leah works with Beth Bernhardt and the Conference planning group on the content of the program. Leah also manages the Conference website <http://charlestonlibraryconference.com> and *Against the Grain* website the-grain.com, contacts potential advertisers and sponsors, and manages the publication of the Conference Proceedings by Purdue University Press.

Toni Nix handles the Vendor Showcase and *Against the Grain* advertising. Sharna Williams coordinates all registrations and manages the Juried Product Development Forums. Regina Semko retired as previous long-time registrar of the Conference. Regina was with the Conference for over ten years and saw many changes over her tenure with the Conference. And, of course, the founder, Katina Strauch, continues to be both behind and at front and center in the scene! Katina is now Assistant Dean for Technical Services and Collection Development at the Addlestone Library.

The content planning group at present, numbering over sixteen members and chaired by Beth Bernhardt for the past six years, consists of librarians, publishers, vendors, and consultants. The primary organization and content of the plenary sessions is decided by this group. Proposals for concurrent sessions are submitted online and a small group makes selections, at times consulting specific members of the content planning group. Members of the content planning group are mindful of the content and evaluations of both the plenary sessions and the concurrent sessions. The content planning group holds several regular conference calls during the year.

The Conference design offers opportunities for corporate sponsors, some of whom underwrite a morning or afternoon coffee break or the Southern—ham and biscuit—breakfast on Saturday. They often invite groups of their customers for dinner on Friday evening.

For those attendees not being feted by a vendor or publisher on Friday evening, the Conference sponsors group dinners, called Dine-Arounds, at several local restaurants with a sign-up sheet at the information booth. Those dinner groups meet in the Francis Marion lobby and are guided on a walk to their chosen restaurant. Dine-Arounds underscore that sense of community among Conference attendees, which is promoted by its very structure in a city famed for Southern hospitality. In the same spirit of community and friendliness, the Conference feted long-time attendees at its 25th anniversary in 2005 with a booklet featuring the career biographies of 50 individuals from all walks of the information profession who had influenced this Conference's long-term success.

Organizing committee members audit some of the breakout sessions and may report in *Against the Grain*, a publication emanating from the Conference, but not limited to Conference reporting. *Against the Grain* is mailed bimonthly to all Conference registrants for the year following a Conference and is available via www.against-the-grain.com/. For many years, Ramune Kubilius has managed the reports from Charleston Conferences for *Against the Grain*.

LEGACY AND PUBLICATIONS

Papers from the Charleston Conferences have always been considered worthy of publication and sharing. As

noted earlier, several of the papers from the very first Charleston Conference were published in *AB Bookman's Weekly*.

Beginning in 1983, Scott Bullard, editor of *Library Acquisitions: Practice and Theory* published by Pergamon Press, began to publish many of the papers from the Charleston Conferences. *Against the Grain* published the proceedings in 2000 and Greenwood Publishing Group/Libraries Unlimited published the proceedings from 2001 to 2009. In 2009 the Conference entered into an agreement with Purdue University Press to publish the future proceedings. Purdue University Press is also publishing a Charleston Insights monograph series building on important issues and trends from the Conferences. The first Charleston Insights monograph published in 2012 was by copyright guru Lolly N. Gasaway of UNC-Chapel Hill entitled *Copyright Questions and Answers for Information Professionals*. More volumes from the Charleston Insights are in the works.

In 1997, Mario Casalini, President of Casalini Libri in Fiesole, Italy, approached Katina about starting a conference like Charleston in Italy. The Fiesole Collection Development Retreats were begun in April, 1999, and many of the presentations are freely available at <http://libraries.casalini.it/retreat/>.

In 2006, ABC-Clio began the annual Vicky Speck ABC-Clio Leadership Award. Vicky Speck edited many Charleston Conference proceedings with Rosann Bazirjian before her untimely death. Recipients of the Vicky Speck Award to date have been Anthony Watkinson, Jack Montgomery, Beth Bernhardt, Heather Miller, Eleanor Cook, Glenda Alvin, Ramune Kubilius, Leah Hinds, and Tony Horava.

Several companies give scholarships to help attendees defray the cost of attending the Conference. EBSCO, Harrassowitz Verlag, Swets, and IGI Global are among those frequent donors.

VALUES

The Charleston Conference's unique appeal lies in its relatively small size, broad-to-specific mix of presentation topics; close interactions between library-related professionals, scholarly publishers, aggregators, and vendors; no exhibits conflicting with sessions; compact venue; overall aura of informality; and a structure that fosters a "complete immersion" experience.

The Charleston Conference sticks to the set of values that the organizers consider essential to its operation. The atmosphere must be informal and welcoming so that people can say what they think. Allow *humor* and *levity*. Ly said, "many a truth is said in jest." Humor goes a long way to create a lively and friendly atmosphere. The programming must be *flexible*, allowing time for last-minute, timely additions to the program. The structure must be *dynamic* so that changes can be made to the structure of the programming frequently. It is important to *surprise* attendees with

innovative programming. Avoid *groupthink*; peer review is good and necessary, but we all have a tendency to reward/accept what is the conventional wisdom. Acknowledge that new and *good ideas can come from anywhere* and that a library technical assistant or a "low person on the totem pole" can have just as valid an idea or concept as the CEO or Library Dean. When sessions are suggested, evaluate the idea and work with the presenter to make his or her point in a way that will increase its understandability to the audience. *Try not to turn down ideas out of hand*. Remember—*everyone has a good idea*. Take chances with programming, plenary or concurrent. Try what other conferences won't do or can't do. Do not be overly bureaucratic. Be positive and smile at all times. The Conference founder tries to be *impartial*. Remember—"Nothing will ever be attempted if all possible objections must first be overcome" (Samuel Johnson, 1709–1784).

The added charm of the Charleston, South Carolina, setting featuring fine, moderately priced restaurants, obvious and extensive historical significance, and artistic and recreational opportunities plus sheer physical beauty buoys the Conference's appeal and contributes to its success. The vision and vigilant guidance of a single individual, Katina Strauch, aided by a coterie of hard-working assistants, has served to keep the Conference high on the desiderata list of most librarians—both in the United States and international.

THE FUTURE

The Charleston Conference began as an idea nurtured by a group of librarians, publishers, and vendors. It continues to be nurtured by those same categories of individuals who love books, libraries, information, and knowledge. What is certain is that it will continue to evolve. Long may it continue.

Editor's note: Many people have helped with this history of the Charleston Conference. Special thanks are extended to Julie Arnheim, Shirley Davidson, Leah Hinds, and Mike Markwith along with Katina Strauch, Charleston Conference Founder.

Chartered Institute of Library and Information Professionals (CILIP)

Tim Owen

Chartered Institute of Library and Information Professionals (CILIP), London, U.K.

Abstract

The Chartered Institute of Library and Information Professionals (CILIP) is the leading professional body for librarians, information specialists, and knowledge managers in the United Kingdom. It has members both in the UK and in approximately 100 countries throughout the world. Its members work in all sectors, including business and industry, science and technology, further and higher education, schools, local and central government, the health service, the voluntary sector, national and public libraries. CILIP was formed in April 2002 as a result of the unification of the Library Association (founded in 1877) and the Institute of Information Scientists. CILIP is the only body in the United Kingdom to accredit university courses in library and information studies, and its Royal Charter empowers it to award Chartered professional status to Members who fulfill its professional criteria.

CILIP is governed by a Council and an Executive Board, supported by a number of special Committees, Panels, and Boards. It provides a full range of services to its members, details of which can be found on its web site at <http://www.cilip.org.uk>. In 2008 CILIP included approximately 21,000 members and offered its services to approximately 15,000 people engaged in library and information work who are regular customers of CILIP Enterprises.

INTRODUCTION

The Chartered Institute of Library and Information Professionals (CILIP) is the leading professional body for librarians, information specialists, and knowledge managers in the United Kingdom. It has approximately 21,000 members, both in the United Kingdom and in around 100 countries. Its Members work in all sectors, including business and industry, science and technology, further and higher education, schools, local and central government, the health service, the voluntary sector, national and public libraries. CILIP was formed in April 2002 as a result of the unification of the Library Association and the Institute of Information Scientists.

CILIP's goals are to position the profession at the heart of the information revolution; develop and enhance the role and skills of all its Members; present and champion those skills, together with new ones that will be acquired through continuing professional development; and ensure that individuals, enterprises, and not-for-profit organizations have ready and timely access to the information they need.

CILIP is the only body in the United Kingdom to accredit university courses in library and information studies, and its Royal Charter empowers it to award Chartered professional status to Members who fulfil its professional criteria.

CILIP is governed by a Council and an Executive Board, supported by a number of special Committees, Panels, and

Boards. It provides a full range of services to its Members, details of which can be found on its web site at <http://www.cilip.org.uk>.

MISSION

CILIP's mission is to

- Set, maintain, monitor, and promote standards of excellence in the creation, management, exploitation, and sharing of information and knowledge resources.
- Support the principle of equality of access to information, ideas, and works of the imagination, which it affirms is fundamental to a thriving economy, democracy, culture, and civilization.
- Enable its Members to achieve and maintain the highest professional standards in all aspects of delivering an information service, both for the professional and the public good.

GOVERNANCE

All aspects of CILIP's work are governed by its Council, supported by Committees, Panels, and Boards drawn from the Members of CILIP, usually through a process of annual elections. Members can also make their voice heard through the Annual General Meeting when the

annual report and accounts of CILIP are presented for scrutiny by the Membership at large.

In this process of governance and accountability, the Honorary Officers have an important part to play. The President of CILIP is elected annually by the Membership at large with the President, President-Elect, and Past President forming three of the six Honorary Officers. The Honorary Treasurer is also elected by the Membership at large, while the Chairs of Council and of the Executive Board are elected by the Council at the first meeting of the year.

CILIP plays a major role in the formulation of policy and development of service delivery across the library and information domain. To assist with this, CILIP has created a range of Advisory Panels covering specific areas of policy, representing key sectoral interests, and providing a locus for consideration of particular aspects of professional activity.

CILIP is a democratically accountable Membership body, and this process of democratic governance is mirrored by CILIP's Branches and Groups, which also hold elections to their various offices and Committees.

Council, Executive Board, Committees

CILIP's governing body is its Council, composed of representatives of Branches and Groups, a number of Councillors elected nationally, and the Honorary Officers of the organization. CILIP is a registered charity and Councillors are the Trustees of the charity.

The Council meets three or four times every year to decide on major issues of policy and resource allocation, scrutinize the work of its various Committees, and review the Regulations that govern the ways in which CILIP conducts its business. As a Chartered Institute, CILIP has a Royal Charter and associated Byelaws that are subject to approval by the Privy Council. These set a broad framework within which the details of rules and procedures are determined by the Council.

In between meetings of the Council, matters of policy and resource allocation and the overall management of CILIP are dealt with by the Executive Board, which also has responsibility for the organization's equal opportunities' policy and practice. The Executive Board reports to the Council on matters affecting general policy, legal and parliamentary business, on developments proposed in the work of the Institute, and on business not assigned to other Standing Committees, and acts on behalf of the Council, in an executive capacity, in matters of urgency.

In addition, there are three broad areas of Committee work to cover in detail the various activities of CILIP:

1. First, at the heart of any professional body are processes of professional development and standards of professional practice. In this area, the Committee

structure covers activities such as the accreditation of courses in librarianship and information science, the framework of qualifications awarded by CILIP, the code of professional conduct, the work of Branches and Groups, and other matters related to the profession.

2. Second, there are the areas of ethics, discipline, and professional conduct, which are also covered by the Committee structure.
3. Finally, there is CILIP's portfolio of Enterprises, which generates more than half of the income used to fund the organization. To oversee these income-generating activities, CILIP has an Enterprise Board, and also an Editorial Board to advise the Editor of CILIP's monthly professional magazine, *Update*.

CILIP's Committees and subordinate Panels include the following.

Policy Development Committee

To formulate and develop an effective program of Library and Information Services (LIS) policy at the national and international levels and to promote good practice in policy implementation. Its Panels include:

Youth and Schools' Panel: To advise Council, develop policy, and promote good practice in relation to LIS to young people.

Post 16 Learning Panel: To advise Council, develop policy, and promote good practice pertaining to LIS as they relate to Post 16 Learning.

Public Libraries' Panel: To advise Council, develop policy, and promote good practice in relation to the Public Library Service.

Workplace and Information Services' Panel: To advise Council, develop policy, and promote good practice in relation to LIS in the "workplace" sector and in relation to the work of independent information specialists.

International Panel: To oversee the international work of CILIP, including the implementation of its international policy and the conduct of international relations.

Preservation and Conservation Panel: To formulate policy and initiate action on issues of preservation, conservation, security, and heritage whether written, visual, printed, spoken, or electronic.

Freedom of Information Panel: To examine the emerging statutory and regulatory framework relating to access to information in the United Kingdom and Europe and to advise CILIP on how to promote the best interests of the public and users, and how to maximize opportunities for CILIP members and the LIS profession in this area.

Professional Development Committee

To formulate policies, initiate action, and monitor performance in matters relating to the qualifications framework and structure (including Chartered status and all aspects of the scheme for Continuing Professional Development) and to the framework of Course Accreditation. Its Boards include:

Chartership Board: To manage all matters relating to applications for admission to Chartered Membership and Fellowship of CILIP (excluding Honorary Fellowships); to establish and maintain standards for approved training programs, submissions for Chartered Membership, and submissions for Fellowships; to assess training programs designed to fulfil the requirements for admission to the Register; to assess applications for Chartered Membership and make decisions on their acceptability; to assess applications for Fellowship and make decisions on their acceptability; to advise the Professional Development Committee on any matters relating to admission to the Register of Chartered Members, including the regulations governing the award of Chartered Membership and Fellowship; to establish and maintain a program of Continuing Professional Development for Chartered Members; to establish and maintain a program of certification of Affiliate Members.

Accreditation Board: To manage all matters relating to applications for approval of courses for the purpose of admission to the Register; to apply the Procedures for the Accreditation of Courses as approved by Council; to assess courses submitted for approval and make decisions on their acceptability; to conduct such enquiry as may be necessary to determine the suitability of overseas qualifications for approval; to advise the Professional Development Committee on any matters relating to the approval of courses, including the regulations governing their acceptability.

Professional Practice Committee

To formulate policies, initiate action, and monitor performance in matters pertaining to Branches and Groups, issues of ethics and standards including the Code of Professional Conduct, membership recruitment, and in matters relating directly to personal members including membership benefits. Its subordinate panels include:

Ethics Panel: To develop the Code of Conduct and Code of Professional Practice for CILIP and to deal with any matters related to the ethics of the library and information profession.

Membership Recruitment and Retention Panel: To develop and oversee strategies for Member recruitment

and retention including market research into Membership satisfaction and the development of Membership benefits.

CILIP Enterprise Board

To oversee the affairs of CILIP's Enterprises in such a way that professional concerns are supported while achieving maximum income generation. Its subordinate bodies include:

Facet Publishing Advisory Panel: Provides a sounding board and guidance for the publishing team, particularly in relation to the publishing program, ensuring that it is of a high standard and reflects the needs of the information community.

Training and Development Panel: Provides a sounding board and guidance for the development of CILIP's training and development function, ensuring that it reflects the needs of CILIP members and their employers, and the wider information community.

Update Editorial Board: Communicates the views of members to the Editor to ensure that members of CILIP receive a relevant and high-quality magazine, which is in touch with issues of concern and relevance to the profession.

Umbrella Planning Sub-Committee: Works with the Conference Department, to help plan a biennial conference that both reflects the current training needs and interests of members and provides an effective meeting and networking opportunity for all CILIP members.

BRANCHES AND GROUPS

CILIP has 12 branches, one for each of the English regions plus CILIP in Scotland, CILIP Cymru for Wales, and CILIP Ireland. All CILIP Members are automatically assigned to one of the 12 Branches and can choose whether they wish it to be based on their home or work address. All Branches receive a central grant from CILIP to allow them to produce regular newsletters and arrange meetings for their Members.

In addition, CILIP has over 20 special interest groups. Membership of two groups is included in the CILIP subscription, and Members may join others for a nominal fee. CILIP's special interest groups include:

Affiliated Members: A special category of CILIP Membership for paraprofessional and other library and information workers, whose National Committee runs special events and publishes a newsletter.

Branch and Mobile Libraries' Group: For staff working in smaller libraries in all types of public library

service, and particularly those working on or with mobile libraries.

Career Development Group: Encourages Members to involve themselves in all aspects of professional activity and is committed to giving a voice to newer Members of the library and information profession.

Cataloging and Indexing Group: Unites Members engaged or interested in the organization and retrieval of information and in the planning, production, maintenance, and exploitation of library catalogs, bibliographies, and indexes.

Colleges of Further and Higher Education Group: Promotes the role of LIS, and of the profession, in further education, higher education, and sixth form colleges.

Community Services Group: Under the banner “information, equality, opportunity”, the Group promotes equal access for all communities to LIS, and combats disadvantage.

Diversity Group: Newly formed in 2003, the Group promotes and celebrates diversity within the library and information profession.

Education Librarians' Group: Concerned with the provision of library and information services to all involved in education as a profession, or the study of education.

Government Libraries' Group: Represents the professional interests of library and information workers in Government Departments, Agencies, Parliamentary and National LIS.

Health Libraries' Group: Unites all those working or interested in LIS for medical, nursing, and allied health professions, for people with disabilities and health problems, the housebound and those in residential care, and for carers and patients in hospital.

Industrial and Commercial Libraries' Group: Represents library and information workers in a wide range of commercial and industrial workplaces, and those acting as independent consultants. Also includes an Aerospace and Defence Librarians' Sub-Group.

Information Services' Group: Supports Members' interests in the provision of information services by promoting activities that improve the effectiveness of information provision to all sectors of society.

International Library and Information Group: Unites Members worldwide who have a strong interest in international work, fostering good international relations, encouraging closer understanding and contributing to the development of library and information services overseas.

Library and Information History Group: Aims to raise awareness of library and information heritage within and beyond the profession, frequently through activities with an international flavour.

Library and Information Research Group: Promotes the value of information research and links research with practice.

Local Studies' Group: Improves public and professional awareness of local studies' library and information services and the valuable role they play within their community.

Multimedia Information and Technology Group: Aims to unite Members engaged or interested in multimedia information and technology developments within the profession, enabling communication and promotion of professional interests.

Patent and Trade Mark Group: Acts as a collective voice for Members involved in patent and trade mark searching and other related information matters in dealing with Government and other official bodies, both nationally and internationally.

Personnel, Training, and Education Group: Provides a focal point for study and discussion of every aspect of personnel work (including training) relating to staff in library and information services and to professional education.

Prison Libraries' Group: Unites Members concerned with the provision of library and information services to penal establishments and serves as a focus for staff who could otherwise feel isolated owing to the nature of their working environment.

Public Libraries' Group: Concerned with all aspects of public librarianship, including standards, staffing, service delivery and promotion, with Membership open to all interested in the work of public libraries.

Publicity and Public Relations Group: Demonstrates to the library and information profession that continuous and planned public relations is essential in every type of library and information service.

Rare Books' Group: Unites library and information workers responsible for collections of rare books, manuscripts, and special materials with other interested individuals.

Retired Members' Guild: Enables retired library and information workers to keep in touch with each other, participate in activities, and assist CILIP in promoting library and information services.

School Libraries' Group: Promotes school libraries and school library services as being essential to all areas of the curriculum, to enable the exploitation of a wide range of resources, develop pupils' information skills, encourage the reading habit and support equal opportunities and multicultural education.

The UK Online User Group (UKOLUG): Advancing the effective use of electronic information resources. The national user group for online, CD-ROM, and Internet searchers, aiming to act as a user forum and also as a consumer group to represent users' interests within the information industry.

University, College, and Research Group: Concerned with the interests of library and information specialists in national, research, university, and other higher-education libraries, including playing a significant part in continuing professional development.

Youth Libraries' Group: Works independently and with other professional organizations to preserve and influence the provision of quality literature, LIS for children and young people in public libraries, and school library services.

MEMBERSHIP

To make sure that every level of our profession is represented, CILIP offers a number of different categories of membership:

Chartered: Member CLIP (MCLIP)—Chartered Members who have met the standards for admission to the professional register through demonstration of professional competence. Fellow CLIP (FCLIP)—Fellowship is awarded for achievement and contribution to the profession.

Associate: For members who are eligible to Charter (i.e., have undertaken an accredited course or have met work requirements).

Honorary Fellow: For persons who, in the opinion of Council, have rendered distinguished service in promoting the objects of the Institute. Nominations may be made by members, Branches, Groups, or committees and subcommittees of Council.

Student Member: For people in full or part-time education on an accredited course in library and information science in the United Kingdom, and graduate trainees on pre-postgraduate experience.

Affiliated Member: Any person working in a post within a LIS or information service that does not require professional qualifications.

Supporting Member: For people interested in LIS.

Overseas Member: For any person in the above categories but resident overseas.

Institutional Membership: For organizations working in or interested in the library and information field.

Suppliers' Network: For members of the library and information supply industry, to develop a closer dialog and program of joint action.

PROFESSIONAL EDUCATION AND QUALIFICATIONS

CILIP currently accredits undergraduate and postgraduate library and information courses in universities throughout the United Kingdom. Courses accredited range from first degrees to postexperience courses, where candidates are

expected to have previous library and information experience at a professional level. Courses come in all forms—full- and part-time, face-to-face or distance learning—and often in combination with other subjects such as business or health information, art history, or languages. All are regularly reaccredited by CILIP's experts, to ensure that they remain up-to-date, relevant to today's issues, and effectively delivered.

In addition, there are courses leading to para-professional/vocational qualifications that are designed to assess levels of competence in a current job. They are designed to improve practitioners' chances of employment and promotion by honing their skills and helping them demonstrate their commitment to the profession. They provide a combination of practical experience and theoretical knowledge and can help candidates find their first job in library and information work.

Chartered Membership

Chartered Membership is the first level of professional qualification awarded by CILIP. Most Members gain Chartered Membership 2 or 3 yr after graduating. It is open to any Member who fulfils the requirements of the Byelaws and complies with the regulations laid down by Council. These include holding academic qualifications in librarianship and information management that are approved by CILIP, having been in Membership for a minimum of 1 yr and having had a period of practical professional experience on which to base an application for Chartered Membership.

The award of Chartered Membership is based on evidence of continuing professional development in practice and on the ability to learn from experience. It is not a re-examination of the theoretical knowledge acquired on an information studies' course. Candidates seek to demonstrate how that knowledge has been applied and what has been learned as an outcome of that application. Gaining Chartered Membership provides concrete evidence of professional development and progression since the completion of academic studies.

Application for Chartered Membership is made through submission of a two-part application. The first part is a form on which candidates must provide information about the knowledge and skills they have developed since gaining their information studies qualification. The second part is a portfolio of evidence of continuing professional development. There are two routes to Chartered Membership. One requires completion of a period of supervised training, the other a period of self-directed continuing professional development.

1. Route A: One-year full-time equivalent work experience following a CILIP-approved training and development program supervised by a Chartered Member. Qualifications required: CILIP accredited degree.

2. Route B: Two-year full-time equivalent work experience without direct supervision following a Personal Development Plan. Qualifications required: CILIP accredited or other approved qualification.

The achievement carries with it the right to the designation Chartered Member of the Chartered Institute of Library and Information Professionals and the right to the use of the postnominal letters MCLIP.

Fellowship

Fellowship is the highest professional qualification available to Members of the Chartered Institute of Library and Information Professionals. It is open to any Corporate Member who has been on the Register and in professional practice for at least 5 yr. full-time or its equivalent. Professional practice includes any aspect of librarianship of information work. Fellowship signifies that a Chartered Member has developed the potential identified by that award and has applied an increasing level of professionalism both through personal professional practice and the contribution made to the profession at large.

Candidates for Fellowship have to demonstrate that they have built on the potential identified by the award of Chartered Membership, through developing the ability to carry out demanding tasks and handle complex professional issues and by making a contribution to all or part of the profession. At this level, the selection of material for submission is of considerable significance. Work presented for the award of Fellowship will almost invariably contain an element of originality, demonstrating intellectual and professional development.

Occasionally, a Member who has not become a Chartered Member may be allowed to make an application for direct admission to Fellowship. Such a candidate must demonstrate that the level required for Chartered Membership has been achieved by some other means (for example, by an equivalent qualification gained in another country).

The achievement carries with it the right to the designation Chartered Fellow of the Chartered Institute of Library and Information Professionals and the right to the use of the postnominal letters FCLIP.

Framework of Qualifications

The CILIP Corporate Plan 2002–2005 stated that CILIP must

provide Members with the means to ensure that their expertise is recognised by the wider community, and to enable them to extend that expertise, so that they can remain abreast of new developments and compete effectively in the employment marketplace. It can do this by ensuring that CILIP's framework of academic and professional qualifications remain rigorous and credible, by

providing new forms of access that recognise paraprofessional roles and nonconventional routes to qualification . . .

Consequently, CILIP has been developing a new Framework of Qualifications, which it is committed to implementing by March 2005. The Framework is based on research and analysis of the skills and competences needed by staff working in LIS in the 21st century, and it will allow for multientry points and progression routes, catering for differing portfolios of experience and qualifications.

The Qualifications Framework introduces a Certification Scheme for Affiliated Members and a Revalidation Scheme for Chartered Members. The Corporate Plan also articulates the need for CILIP's current Body of Professional Knowledge to be reviewed and updated. Following discussion within both the Accreditation and Chartership Boards, and the Skills and Competencies Steering Group (now called the Framework of Qualifications Steering Group), it was agreed that this work would be undertaken in several stages.

A think tank of representatives of the sector has been meeting to undertake a preliminary investigation. This will be developed and refined through further consultation and debate among a wider stakeholder group, including representatives from outside the library and information sector. The work has been undertaken by a joint working group, under the direction of CILIP's Chartership and Accreditation Boards. The final document will provide a crucial underpinning to the work of designing and developing new Regulations for Chartered Membership, including Fellowship, and also to the review of the Accreditation procedures for assessing programs of academic study in the discipline.

Additionally, CILIP is taking forward various initiatives to support work on its Equalities agenda; this includes investigation of a bursary scheme information and library staff from minority ethnic groups to enable study for professional and paraprofessional qualifications.

Overseas Qualifications

CILIP has a reciprocal agreement with The American Library Association and The Australian Library Association, which means that academic qualifications accredited by those bodies are recognized in the United Kingdom. This allows graduates holding American or Australian bachelor's and master's degrees in library and information studies to apply for posts asking for qualified librarians and information professionals in the United Kingdom.

Qualifications from European Union member states are also recognized in the United Kingdom, provided they have been assessed as being at the degree level or its equivalent.

Other qualifications are individually checked and inquirers should contact the Qualifications section at CILIP.

All inquirers whose qualifications are accepted by CILIP are eligible to register to Charter with CILIP.

ETHICAL PRINCIPLES AND CODE OF PROFESSIONAL PRACTICE

CILIP has drawn up guidelines to provide a framework to help library and information professionals, who are Members of CILIP, to manage the responsibilities and sensitivities that figure prominently in their work. There is a statement of Ethical Principles and a more extended Code of Professional Practice, which applies these principles to the different groups and professionals to which its Members must relate. The Code also makes some additional points with regard to professional behavior. Given the diversity of the information profession, it is inevitable that not every statement in the Code of Professional Practice will be equally applicable to every Member of CILIP. However, the Ethical Principles ought to command more general support, even though some Members may not feel the force of each one of them to the same extent in their day-to-day experience. The Principles and Code assume that respect for duly enacted and duly enforced law is a fundamental responsibility for everybody. However, the Principles and Code may provide additional guidance where there appears to be a conflict of responsibilities.

By the terms of its Royal Charter, CILIP has a responsibility to “the public good.” It is therefore anticipated that its Ethical Principles and Code of Professional Practice may be of interest well beyond the immediate limits of the Membership of CILIP, both to those whose work bears close comparison with that of CILIP Members and to those who may, from time to time, want a clear statement of our ethical principles and what we consider to be good professional practice.

Associated with these Principles and Code, there is a growing collection of practical examples, illustrating how information professionals and others can use the Principles and Code to help them cope with the ethical dilemmas they may face. In further support of the Principles and Code, CILIP has established an Ethics Panel of experienced members of the profession, and they and the professional staff of CILIP are available to Members who may need additional help in resolving ethical issues. In those instances where there appears to have been a significant breach of the Code of Professional Practice, this may be a matter for the CILIP Disciplinary Committee. According to the Regulations, the Disciplinary Committee is required to have regard to the Code of Professional Conduct in its work.

SERVICES TO MEMBERS AND OTHERS

CILIP provides a comprehensive range of services to its Members, with the overall aim of helping them remain

both informed and employable. In addition, CILIP Enterprises, the Institute’s revenue generating arm, provides services to all who require them, usually with discounts for CILIP Members. Further details of all these services can be found on CILIP’s website—<http://www.cilip.org.uk>.

CILIP’s direct services to Members include:

Qualifications and Professional Development

- Assessment and accreditation of undergraduate and postgraduate university courses in information and library studies.
- Advice on academic study and professional qualifications in library and information work.
- Chartership—full support from expert CILIP staff throughout the process of becoming professionally qualified.

Information and Advice

- Dedicated enquiry service for members’ personal queries—including free searching of selected commercial databases.
- CILIP *Daily News*, *Weekly Information World*, and *International News Bulletin*—member-only e-mail news and current awareness services, delivered direct to CILIP Members’ desktops (on-line sign-up required).
- Confidential one-to-one advice and guidance on professional issues and personal development.

News and Comment

- *Library & Information Update*—CILIP’s monthly magazine, including in-depth coverage of professional and industry news and features (also available separately on subscription).
- *Library & Information Gazette*—CILIP’s fortnightly tabloid newspaper with Institute-related news, views, comment, and approximately 12 pages of jobs (available to CILIP members only).

Networking and Further Support

- Free membership of the appropriate regional CILIP Branch and two special interest groups (further groups can be joined at nominal charge).
- Exclusive use of CILIP’s Information Centre, which includes a library, e-mail and Internet facilities, meeting area, and Members’ lounge (available to guests when accompanied by a CILIP Member).
- Libex International Library and Information Job Exchange—Clearinghouse for U.K. CILIP members interested in arranging job exchanges with library and information professionals in other countries.

- Discounts on other CILIP products and services listed below, plus a growing range of exclusive bonus benefits—details are available at <http://www.cilip.org.uk>.

Details of all other services available from CILIP (usually available to nonmembers for a charge and to Members at a discount) are also given on its website, <http://www.cilip.org.uk>. Services include:

Library and Information Update (including Buyers' Guide supplement)

- *Library and Information Update*—A monthly magazine with in-depth articles and news on current library and information issues, supplied automatically to Members and available to others on subscription.
- *Update Buyers' Guide*—Quarterly supplement to *Library and Information Update* listing library and information service suppliers' products and services. Also available on-line.

LIS Jobnet

- On-line summary of currently available jobs on offer, available through the CILIP website (details also mailed exclusively to CILIP members in *Library & Information Gazette*).

Facet Publishing

- CILIP's own publishing house, widely regarded as the best source of quality, timely, and useful books for library and information professionals worldwide. Details of available titles and sample chapters are accessible via the CILIP web site, and CILIP Members enjoy a 20% discount on all titles.

INFOmatch

- CILIP's in-house recruitment consultancy, offering services to recruiters, and jobseekers. Covers permanent, temporary, and contract employment. Infomatch services are open to all, but the consultancy also offers special job search advice services to CILIP members.

CILIP Training and Development

- Comprehensive program of training workshops and executive briefings, provided both in-house and on-site. Sessions are usually open to all, but CILIP Members enjoy discounts of up to 30% on course fees.

CILIP Conferences

- CILIP's in-house conference management service, creating tailor-made events for CILIP organizations and outside clients.

CILIP Consultancy Services

- Specialist library and information consultancy with a track record in a wide range of projects and disciplines.

CONCLUSIONS

Vesting Day on April 1, 2002 saw the birth of CILIP, but the new organization will not be fully grown for some time after this. An action plan was mapped out for the transitional period to December 2004 during which a number of important elements of the new organization were being put in place:

- A new structure of qualifications.
- New arrangements for regional Branches in England.
- A new code of conduct and ethics.
- New arrangements for Special Interest Groups.
- A new subscription framework.
- A new web site.

For some time, CILIP will continue to be a "work in progress"—in consultation with the Membership—while at the same time providing a full range of products and services for CILIP Members and the wider library and information community. For up-to-date information on CILIP and its activities, readers are advised to revisit its website regularly—<http://www.cilip.org.uk>.

Chemistry Literature and Its Users *[ELIS Classic]*

Judith N. Currano

University of Pennsylvania, Philadelphia, Pennsylvania, U.S.A.

Abstract

The chemical literature is large and varied, crossing many other scientific disciplines. It includes review sources, which summarize past work done in a particular field and are excellent background reading; primary literature, such as research articles in journals; indices and abstracts, which help one to find review and primary documents; catalogs for books, chemicals, and equipment; and handbooks, which present values for physical and chemical properties and the references that report them. There are many nonkeyword access points to all of the various types of literature. Names, formulae, structures, sequences, and other unique identifiers help chemists to locate compounds, while substructure, reaction, and sequence searching are powerful tools for finding structurally similar substances and their reactivity.

INTRODUCTION TO CHEMISTRY AND THE CHEMICAL LITERATURE

Chemistry has been described as “the central science,” in part because it has close links to all other sciences. Mathematics is used to describe some physical phenomena, and a basic knowledge of physics is necessary to understand how chemicals behave and why reactions occur. Chemistry takes place in biological systems, fuels transportation devices, and produces cleaning products, medicines, and personal adornments, such as cosmetics and jewelry. Anyone who has baked a cake, lit a candle, or thrown salt on a driveway to melt ice in the winter has set a chemical process in motion.

Chemistry has traditionally been broken into five subdisciplines: organic chemistry, inorganic chemistry, physical chemistry, biological chemistry, and analytical chemistry. Organic chemists are concerned with the synthesis, reactions, and properties of compounds containing carbon. Inorganic chemistry is a vast field; some of the many substances studied by inorganic chemists are elements, compounds or salts containing no carbon, alloys, glasses, ceramics, and substances that combine metals with organic molecules (coordination compounds). Physical chemists study the underlying physical processes involved in chemical behavior, while biochemists look at the chemistry that occurs in biological systems. Analytical chemistry is used, to some extent, by all of the above groups; it involves the characterization of chemical substances and the study of the structure of matter. Although undergraduate-level chemistry still tends to be divided along these lines, chemical research is becoming increasingly interdisciplinary, such that other subcategories and “overlap categories” (theoretical chemistry, medicinal chemistry, polymer chemistry, organometallic chemistry, environmental chemistry, nanochemistry, energy research, etc.) are becoming the norm, rather than exceptions.

Researchers in each subdiscipline ask different types of questions and seek different kinds of information, but all have certain things in common. They are all concerned with chemical substances or processes, whether they perform reactions using them in the lab or model them on a computer. In order to locate information successfully, chemists must understand the structure of the chemical literature, be familiar with its unique access points, and make use of specialized search techniques.

STRUCTURE OF THE CHEMICAL LITERATURE

Primary Literature

Like the literature of most disciplines, the chemical literature is divided into two basic categories, primary and secondary sources. As a general rule, primary sources contain the results of original research, as well as experimental procedures. Since chemists are constantly seeking to build on the work of others without reproducing it from scratch, they are avid readers. Bench chemists, or chemists who work with chemicals in a laboratory, rely on the primary literature to get recipes and instructions for running reactions, and all experimental and theoretical chemists read to stay up-to-date with recent advances in their fields. Commonly used primary documents include: journal articles that describe new research, monographs that consist of collections of original articles, patents, governmental and industrial technical reports, preprints, and some Web sites. Chemists also share information about their research at conferences; however, these meetings do not always result in published conference proceedings. For example, the largest chemistry meetings, the American Chemical Society National Meetings, publish abstracts for talks or posters but have no formal conference proceedings. In recent years, the American Chemical Society

has begun recording and making available online a subset of the talks presented at the meetings, and individual divisions of the society might publish their papers presented at the meetings in serial publications or as *ACS Symposium Series* volumes. Researchers looking for more detailed information from a paper or poster presented at a meeting for which conference proceedings are not available can always try contacting the author directly to get a copy of the material.

Journal articles

The bulk of the primary literature in chemistry is published either as journal articles in peer-reviewed publications or as patents. Academic chemists try to publish in prominent journals with high impact factors or that are central publications in their fields. They tend to publish two different kinds of primary articles describing their research: communications, or letters, which are short pieces intended rapidly to introduce important findings, and articles, which are longer pieces that present more details than communications. Chemists turn to the journal literature for general or specific instructions for a particular reaction, programming code for a simulation, methods of preparing substances, etc. They can use a variety of secondary sources to identify research articles of interest in the journal literature, many of which are discussed later in this entry.

Patents

Not all important chemical research, however, is published in the journal literature. Chemistry is not only an academic discipline; it also has a strong industrial sector. While chemists at companies with large research and development groups do publish in the journal literature, important advances by companies are more frequently *patented*. This gives the company the right to exclude others from using the patented invention for the term of the patent, which is, for example, 20 years in the United States. Patents will only protect the invention in the countries in which they are filed; therefore, if a chemist wants her invention protected in the United States, China, and Japan, she must file her patent with the patent offices in each of these countries. There are several overarching intellectual property organizations, including the European Patent Office, a regional patent office whose patents protect inventions in most European countries, and the World Intellectual Property Organization (WIPO), which administers the Patent Cooperation Treaty (PCT). This treaty allows an inventor to file a single patent application with WIPO and use it to apply for protection within any member country.^[1] Patents for the same invention filed in different countries constitute a *patent family* and contain roughly the same information. Therefore, if a scientist locates a useful patent in a language that he does not read,

it can be helpful to search for that patent's family and see if it contains an "equivalent" patent in a known language.

Chemists file utility patents that protect substances themselves (drugs, agricultural agents, polymers, etc.), methods of producing substances, and scientific instruments or equipment. Within the patent, the scientist must prove that the invention described is novel, useful, and nonobvious. He or she must also present instructions so that someone skilled in the art would be able to reproduce the results. Therefore, in addition to being legal documents, patents are very important scientific documents, presenting the same kinds of recipes and instructions that the journal articles do. It is important to note that a large percentage of the chemistry published in the patent literature is not published in any other place, and so it is wise to consider searching both patents and journal articles when performing an exhaustive search on a subject. Chemists can identify useful patents using the search features on the individual patent offices' Web sites,^[2,3] or by using proprietary resources like the Derwent World Patents' Index, available through the Derwent Innovations Index, or CAS's SciFinder product.^[4]

Publication of primary data

In the early 2010s, many government funding agencies began requiring grant awardees to make the products of their research freely available to any who wanted to benefit from them. Initially, their attention focused on open access journal articles, but this was quickly followed by open data. At the time of this writing, many U.S. government agencies require chemists to include in their grant proposals a *data management plan* describing how data resulting from the project will be preserved and made accessible to other researchers. Whenever possible, the chemists are being asked to make their data available through open access repositories, either at their home institutions or through external entities like FigShare.^[5] Chemists may also choose to deposit data in domain data repositories, such as the Protein Databank and the Cambridge Crystallographic Data Centre, which are discussed further later in this entry. The purpose of this requirement is to allow other scientists to use and benefit from the data gathered from publicly funded projects. Many data repositories supply the data sets with digital object identifiers (DOIs), which others can use to cite the data in their work. Calriviate Analytics tracks citations to data using the Data Citation Index, and this activity may encourage chemists to take citations to data, as well as to articles, into account when evaluating academics for promotion and tenure, although it is still too early to tell.

Secondary Literature

Secondary sources do not directly report research results; instead, they serve as a "key" to the primary literature, and

chemists use them to locate the original research that they require. They can be divided into four further categories. *Review sources* and *handbooks* are edited by experts in the field and aim to supply the most reliable information in their areas. Chemical information professionals occasionally refer to these two categories of literature as the “tertiary literature” to distinguish them from the other two categories, *indexing and abstracting services* and *catalogs*, which are much less judgmental. These resources allow researchers to locate primary documents on a subject of interest but offer little indication of the quality of the information retrieved.

When approaching a new project, a chemist will usually seek background information on the subject, in order to hone the idea and determine which experiments or models to use. A piece of review literature generally serves as an excellent introduction to a subject; an experienced scientist has summarized the literature written in this area and provided an extensive bibliography of primary documents and additional reviews. Once the chemist enters the lab, he or she tends to rely on the primary literature, located using appropriate indexing and abstracting sources, as well as catalogs, to find procedures, suggestions, and even substances or equipment that help to move a project from stage to stage. Handbooks can be invaluable sources of quick information and, most importantly, properties and reactions of compounds. In fact, when searching for properties, it is always best to start with a handbook, which will include both the value of the property and the primary literature reference in which it was reported. The following sections more completely describe each type of secondary or tertiary resource and introduce some of the most important sources of each type.

Review Sources

Review sources in chemistry can be divided into three basic categories: encyclopedias, treatises, and review articles in journals. All are helpful to a scientist attempting to find general or background information on a subject of interest. Of the three categories, encyclopedias tend to treat the most general subjects, while the topics of review articles can be extremely specialized. The problem with review sources, as a category of information, is that they are out-of-date as soon as they are published. Therefore, it is very important to pay attention to the publication date of the source and to supplement an older review with searches of the recent primary literature.

Encyclopedias

Encyclopedias are usually multivolume sets that deal with a fairly broad subject. Some examples of chemistry encyclopedias include the *Encyclopedia of Analytical Chemistry*,^[6] the *Encyclopedia of Chemical Physics and Physical*

Chemistry,^[7] the *Encyclopedia of Inorganic Chemistry*,^[8] the *Encyclopedia of Inorganic and Bioinorganic Chemistry*,^[9] and the *Encyclopedia of Reagents for Organic Synthesis* (EROS).^[10,11] Encyclopedias serve a dual purpose; a scientist can get an overview of a very broad subject by reading large sections at a time, or he or she can pick up quick information and definitions by using the indices and tables of contents. For example, EROS has in-depth articles about various reagents used to synthesize organic molecules. However, using the online edition, a chemist can search for a particular transformation and be taken directly to the point of the article at which this transformation is discussed. Encyclopedias in the field of chemistry are published in both print and electronic formats, with parity between the two formats becoming increasingly rare. It is a monumental undertaking to publish a complete, new edition of an encyclopedia, meaning that they get updated in their entirety rather infrequently. Leveraging the speed of Web-based publishing, publishers can update articles as needed, and many have begun selling “annual updates” to customers who choose to purchase an electronic encyclopedia outright rather than licensing it through an annual subscription. Electronic editions of encyclopedias tend to be much more expensive than their print counterparts.

One of the most important encyclopedias in any area of chemistry is the *Kirk-Othmer Encyclopedia of Chemical Technology*,^[12,13] which is a great starting point in a search for information on a broad or general area of chemistry or chemical engineering. Many articles are about commonly used chemicals and classes of substance and contain information about their production, physical and chemical properties, biological activity, and natural occurrence. Because of *Kirk-Othmer*’s emphasis on chemical technology, many of the articles dealing with chemicals also include information on economic aspects, industrial uses, and safety or hazards associated with the chemical, the first of which can be extremely difficult to find elsewhere.^[13] In addition to pieces about chemicals, *Kirk-Othmer* also contains articles describing chemical processes and pathways, techniques, and instrumentation. It is available in two formats; the fifth print edition, consisting of 26 volumes, began publication in 2004 and was completed in 2007. It is organized alphabetically by concept, with subject and contributor indices. The electronic edition, which contains the same information as the print, can be browsed alphabetically by article title or searched by keywords in any field of the record. It has options that allow the user to search a specific field of the record or limit to articles in a specific subject area or written during a particular time period.

Treatises and review articles

Treatises can range from enormous, multivolume sets, such as *Organic Syntheses*^[14] and *Methods in*

Enzymology,^[15] to short monographs on a subject, like the books in the Oxford University Press *Practical Approach* series. All are written or edited by experts in the field of the volume, and all provide the reader with information that is slightly more specific than that found in an encyclopedia but is still general enough to be understood by someone new to the area. The print editions of the larger sets, including *Comprehensive Organic Functional Group Transformations 1* and *2*^[16,17] and *Comprehensive Organometallic Chemistry 1, 2, and 3*,^[18–20] tend to be kept in library reference collections, although many libraries are now purchasing these types of tools in electronic format, due to the superior searchability and ease of access of that format. As with encyclopedias, the electronic editions tend to be much more expensive than print editions. Comprehensive sets are updated regularly but infrequently, with each updated edition picking up the review of the literature where the previous one stopped. The topics of the sets tend to be fairly broad, and the individual volumes frequently deal with a single subject or a set of subjects in a reasonable amount of detail.

One of the most impressive treatises is the enormous *Houben-Weyl Methoden der Organischen Chemie*, or *Houben-Weyl Methods of Organic Chemistry*, published by Georg Thieme Verlag.^[21] This resource aims to present a comprehensive set of methods of synthesizing compounds and classes of compounds. The first edition was created in 1909, by Theodor Weyl, and it reviews literature dating back as far as 1834.^[22] The current series consists of 183 volumes. In 2000, Thieme decided to extend and update Houben-Weyl with a 48-volume series called *Science of Synthesis*,^[23] released almost simultaneously in print and database format between 2000 and 2008. Mindful of the datedness of review-type publications, Thieme began releasing periodic “Knowledge Updates” to the original 48-volume set; these volumes are aimed at updating information encapsulated in the original set and adding topics not originally included. *Science of Synthesis* can be searched online via its native interface, but articles from it and from its parent series are also referenced in *Chemical Abstracts*, making it easy for chemists to be drawn to information of interest. The online edition features the ability to search by structure or reaction for molecular transformations, as well as detailed text search capabilities. The previous volumes of *Houben-Weyl* are also available online through the *Science of Synthesis* interface, although the search features are not as advanced.

For background information on a more specific subject, chemists tend to turn to books in their library collections. Chemistry books appear in both print and electronic formats, and, at the time of this writing, libraries tend to select one or the other on a case-by-case basis. Chemistry e-books are sold either as individual items or as part of e-book packages, and some publishers allow libraries to pick the purchase option that they prefer, while others use

a single option. Libraries choosing an e-book package get access to all books published that year in the chosen subject area. Some monographs have records in *Chemical Abstracts*, but most can be more efficiently located through a search of the local library catalog, a union catalog, such as OCLC’s WorldCat,^[24] or an e-book aggregator or publisher platform. Monographs can also be discovered by word of mouth, and scientists will frequently recommend books to one another. Many chemistry books are described as “textbooks,” as opposed to “books of original articles”; some of them are actually textbooks, in the traditional sense of the word, but many are simply treatises written by a single author, which provide excellent background information.

The most specific type of review literature is the review article, found either in journals or in books of original articles. Review articles in journals are submitted and undergo the same peer review process as experimental articles. They can be submitted either to journals that publish only review articles, such as *Chemical Reviews*, or journals that publish all kinds of scholarly articles, such as *Science*. Scientists can identify review articles on a subject of interest using indexing and abstracting services, all of which include an option to limit document or treatment types to review articles. The reviews in books do not always undergo as strenuous a review process as those in journals, but they have been requested and edited by the volume editor. It can be more difficult to locate these, as book indexing in indexing and abstracting services is not always consistent or detailed. However, most recent library catalog records include table of contents information in their notes fields; so, a keyword search across all fields in a local catalog will frequently locate books containing an article of interest.

Indexing and Abstracting Services

Indexing and abstracting services in chemistry are not fundamentally different from their counterparts in other disciplines, although they frequently have access points that are unique to chemistry. The most comprehensive index to the literature of chemistry is the gargantuan *Chemical Abstracts*,^[25] produced by Chemical Abstracts Service (CAS), a division of the American Chemical Society. This resource covers all areas of chemistry and currently indexes chemistry articles from thousands of scholarly journals, as well as books, book chapters, patents from 63 different patent-issuing authorities, dissertations, reports, preprints, and Web sites.^[26] The *Web of Science*^[27] provides access to both topical information and citation data for all areas of science and technology, including chemistry. In addition to *Chemical Abstracts* and the *Web of Science*, researchers in specific chemical disciplines use other indexing and abstracting services, as well. Physical chemists may use *Inspec*,^[28] which indexes over 3500 journals in the areas of physics and electronics

and contains information dating back to 1896.^[29] Biochemists prefer information from *PubMed* or *MEDLINE*^[30] and other resources from the *National Center for Biotechnology Information (NCBI)*^[31]; and some inorganic and materials chemists find useful references with the electronic version of *Engineering Index*, *El Compendex*, which dates back to 1884 and contains information on all engineering disciplines.^[32]

Chemical Abstracts

No discussion of the chemical literature would be complete without a look into *Chemical Abstracts*, one of the world's largest indexing and abstracting publications. *Chemical Abstracts* began publication in 1907. Prior to its inception, several other sources, including *Comptes Rendus*, *Bulletin de la Société Chimique de France*, *Index Medicus*, *Engineering Index*, and *Chemisches Zentralblatt*, provided abstracts of American and international chemical literature; American chemistry was highlighted in the *Review of American Chemical Research*, *Chemical Abstracts'* direct precursor, which began publication in 1895 and became a part of the *Journal of the American Chemical Society* two years later.^[33] For a long time, *Chemical Abstracts* relied on volunteer abstractors to write abstracts for journal articles; currently, they take author abstracts and enhance them, making them more informative and easily searchable. Like many other indexing and abstracting services, *Chemical Abstracts* uses a thesaurus of index terms, as well as supplemental, descriptive terms. Its print indices included the Author Index, General Subject Index, Formula Index, Chemical Substance Index, Patent Index, and Ring Index, as well as the Index Guide, which provides searchers with supplemental terms on which to search, and the Registry Handbook, which lists CAS Registry Numbers[®] of newly published substances and substance names.

Chemical Abstracts is currently accessible online via the STN or SciFinder^[4] interfaces. Information professionals in companies and the government prefer the command-line driven STN interface, which allows for superior query generation and great specificity of search options. End user chemists and most academic librarians use the more "intuitive" SciFinder interface, which seamlessly links the CAS Registry database with the Chemical Abstracts and MEDLINE abstract databases, as well as a reaction database called CASREACT. Therefore, a researcher can perform a search for a compound in the Registry, click a single button to get all references that contain preparations of that compound, and then click another button to be taken to all reactions that appear in those references. In addition to these four main databases, SciFinder also incorporates a commercial availability source called CHEMCATS and a regulated chemicals listing called CHEMLIST. These are linked from the compound listings in the Registry, although they can be

accessed by clicking on a chemical structure or CAS Registry Number (see pp. 37–38) from any database in the system.

Chemical Abstracts is most chemists' first stop for information since its literature coverage is so extensive and it handles compounds and reactions better than any other article database. SciFinder was one of the first of the major science and engineering resources to introduce the analyze feature, allowing users to get some "demo-graphics" of a large answer set, such as publication years, prolific authors and institutions, or substances used in the papers; this feature is now standard in many resources, but it still offers chemists the ability to easily refine their queries.

Web of Science

The Web of Science, available from Clarivate Analytics, is a unique database. Its core collection indexes scientific journal literature from over 12,000 sources.^[34] The original electronic database dates back to 1945, but the previous owners, Thompson-Reuters, expanded this coverage with a supplemental back file extending back to 1900. The Web of Science allows topic, author, and institution searching, with a wide range of refinements available. A topic search of the database searches the titles of articles, their abstracts, when available, and author- and indexer-generated keywords. Results can be analyzed according to any category in the articles' records, refined by keyword or other limits, and exported into a usable format for the scientist.

The true power of the Web of Science, however, lies in its ability to perform cited reference searches. While many databases and search systems, such as SciFinder, can link from an article to those that cited it for a limited portion of their coverage, the Web of Science lets users perform a true cited reference search across the entire breadth of the database.^[35] Although each Web of Science record links directly to the articles that cite it correctly, the most comprehensive way of searching for citing references in Web of Science is to use the cited reference search interface. Authors will frequently make mistakes in their bibliographies: citing an incorrect volume number, making a typing error in the page number, inverting the issue number and page numbers, etc. A cited reference search will retrieve all of these variants and allow the user to select those that he or she thinks refer to the original document. By entering the name of the first author, the standard Web of Science abbreviation for the journal title, and the year of publication, the user retrieves a list of documents that match these three criteria. From this list, users can easily see the correct variant (it links to the Web of Science record for the article itself) and can select the other variants that they think actually cite the article of interest.

Another advantage to the Web of Science is the many options that it offers for citation analysis. A researcher can

generate a citation report on any list of results generated through Web of Science searching. While the most common use of the citation report is to determine an author's h-index, one can also look at the citation metrics for a cluster of articles on a topic or published by a journal. The core collection also links to the *Journal Citation Reports (JCR)*,^[36] so, researchers can immediately view basic impact metrics for any article in a result set and can link across to the full JCR in order to view more journal metrics and compare the title with others.

Chemists use citation searching in a very similar manner to other scientists. It is frequently employed by tenure and promotion committees to demonstrate the impact that the scientist has had on his or her field of science. This is frequently done by generating a citation report for that author's publications to locate his or her h-index or by examining the Impact Factors of the journals in which he or she has published. However, it can also be used in more creative ways. If a chemist is having difficulty with a literature search, it can be helpful to perform a cited reference search on one article that is highly relevant to the matter at hand. This will indicate the uses that other researchers have made of that information and can yield some results that a simple keyword search might miss. In addition, the multidisciplinary nature of the resource allows a user to see the applications of chemistry research in other areas of study.

Inspec and Compendex

Inspec's topics lie in the areas of physics, physical chemistry, and electrical and computer engineering, as well as some information science. As a result, it can be quite helpful for chemists examining the physical aspects of a project. One particular boon for chemists using this service is the chemical indexing field, which was first added to the Inspec data structure in 1987.^[37] The chemical indexing claims that it does not include organic compounds, although small molecules like methane and ethane can actually be located, as can fullerenes, which are large, spherical "organic" molecules. The structure of "formulae" in the database is truly unique, and users should refer to the help files for exact formatting. However, in addition to having the chemical's formula, it also includes a list of every element that makes up the chemical or system. Formulae and elements are tagged with indicators of their roles in the paper, which include element, binary, system, adsorbate, and surface. The last two roles make the database very useful for physical chemists interested in systems in which a small molecule or atom interacts with a surface. For these reasons, Inspec is probably the most "chemical friendly" of the databases whose primary focus is not chemistry.

Compendex, which is primarily *Engineering Index* online, employs more traditional keyword searching, supplemented by author and controlled vocabulary

indices. It is strong in materials science; it has good coverage in the areas of nanochemistry and materials chemistry, both organic and inorganic; and it also contains useful information for polymer scientists, fuels chemists, and energy researchers. It does not have any specific chemical search capabilities and thus is most frequently recommended for research topic or author name queries that overlap its fields of study.

MEDLINE, the NCBI resources, and the Protein Data Bank

The information in the National Library of Medicine's (NLM) MEDLINE database currently dates back to approximately 1946 and is devoted to all areas of medicine, including clinical medicine, nursing, medicinal chemistry, biochemistry, and pharmaceuticals. The NLM provides the MEDLINE database free of charge through an interface called PubMed, and it is also available via many different vendors' platforms including CAS's SciFinder and through the Web of Science.

MEDLINE is obviously of great use to biochemists, particularly those interested in studying the chemistry of biological systems or drug development, and many such scientists will turn to PubMed before searching in any other resources. MEDLINE, like *Chemical Abstracts*, is thesaurus driven, and the Medical Subject Headings (MeSH) thesaurus can be viewed online. Many of the subject headings are accompanied by subheadings or aspects, which can be searched on their own; some of the ones that are most useful to chemists are "chemistry," "biochemistry," "isolation and purification," and other similar terms. CAS Registry Numbers were added to MEDLINE records in 1985, and a search in this field will retrieve information written since that date. However, the CAS Registry Number and substance indexing in MEDLINE is not nearly as exhaustive as that in *Chemical Abstracts*.

The other NCBI resources are mainly used by biochemists and molecular biologists. The tools are organized on the NCBI Web site^[31] according to the type of information that they search, including Chemicals & Bioassays, DNA & RNA, Domains & Structures, Proteins, and Literature, and they represent an interesting mix of secondary search tools and deposition databases for experimental data. The literature database PubMed is a true indexing and abstracting service, incorporating MEDLINE records, as well as non-MEDLINE articles that come from MEDLINE-indexed journals, while the other resources are varied and include deposition and curated databases of substances, sequences, gene information, and diseases. Some examples of molecular and substance databases offered through NCBI are Nucleotide, Protein, Structure, Gene, Genome, and PubChem. These sequence data, three-dimensional structures, entire genomes, and small molecules deposited by scientists, as well as references to

these entities in the literature. Additionally, some of the databases, such as Gene, contain summary information prepared by curators to supplement data deposited by submitters, as well as links to additional information resources. The NCBI resources all link seamlessly to one another and to PubMed, making it easy for a searcher to move from one to another. For example, with a few clicks, a researcher can search for articles dealing with a genetic disease, learn about the gene that controls it, link to nucleotides connected to that gene, and end with the three-dimensional structures of the proteins coded by those nucleotides.

Catalogs

Chemists use several different types of catalogs as they search for information. Library catalogs are extremely valuable for determining the holdings of a local library, as well as for locating treatises and review sources. Union catalogs, like WorldCat,^[24,38] can assist chemists who want to examine a broader spectrum of books and periodicals. Most searching in catalogs parallels that done in other disciplines; researchers use title and author searches to locate known items and use keyword searches, as well as the occasional subject heading search, to find items on a topic of interest.

In addition to catalogs of books, however, chemists require other types of catalogs. Since bench chemists are performing reactions and studying substances, they need to purchase chemicals and equipment in order to do their research. There are several popular chemical catalogs, including CHEMCATS, available via links from the Registry file in SciFinder; the Aldrich, Sigma, and Fluka catalogs, which can be obtained by request from the companies or accessed online through their combined catalog^[39]; *ChemSources USA*^[40] and *ChemSources International*^[41]; the PerkinElmer Available Chemicals Exchange (ChemACX)^[42]; ChemExper^[43] and e-Molecules,^[44] free sources that harvest information from many different online catalogs. There are an equal number of equipment catalogs, and glassware and equipment can also frequently be obtained from the Thomas Register,^[45] most conveniently searched online.

Many chemical catalogs provide, in addition to the availability, quantity, and price of the catalog, some basic physical properties. The Sigma-Aldrich online catalog is one of the best catalogs in this regard, including such properties as melting point, boiling point, density, and solubility, as well as links to pdf images of the infrared, Raman, and nuclear magnetic resonance spectra of many substances. This catalog also goes one step further, referencing the compound's location in important handbooks, such as the Beilstein Handbook of Organic Chemistry and the Merck Index.

Chemical companies also provide another useful piece of information for every substance that they sell. Called

Safety Data Sheets (SDS), formerly Materials Safety Data Sheets, these information sources are designed to inform scientists of the hazards involved in working with the compounds that they describe. To do this, they include physical and chemical properties of the substance; its chemical reactivity; information on safe storage, transportation, and disposal techniques; appropriate first aid information; and other useful information to ensure safe use and handling of the substance. The companies are required by law to disclose this information for each substance that they sell, and OSHA regulations require that chemists know the location of the SDS for each substance that they use in the lab. The Internet has become a common location for safety data sheets, and most companies link to the SDS for each substance from its catalog entry. One of the easiest methods of finding SDSs is through a simple Google search for the name of the company that supplied the substance and the term "safety data sheet." A chemist can use any SDS in order to find general safety and hazards information about a substance, but, to fulfill the regulatory requirements, they must keep a copy of the SDS from their specific supplier on file.

Handbooks

Finding physical and chemical properties of substances using indexing and abstracting sources can be like searching for a needle in a haystack. Abstracts are infrequently written to include statements like, "The following physical properties of the new compound are presented in this paper," and index terms, while they may indicate that properties of substances are included, do not always tell which properties of each compound are present. Presenting different properties in an easily read manner is the job of handbooks, a category that includes general and specific handbooks, spectral atlases, and crystallography collections and that falls into the "tertiary" classification of literature. A good handbook will be edited by someone knowledgeable in the field and should include the best possible values for each property presented. In addition to the value of the property, a reference to the primary document from which the value was obtained should be given. This allows a chemist to refer to the conditions of the original experiment and can help to explain inconsistencies in the reported values of properties. Handbooks tend to deal with a particular class or category of compounds; for example, the *The Merck Index*,^[46,47] now owned by the Royal Society of Chemistry, covers only drugs, biologicals, and agricultural agents. However, some handbooks, like the *CRC Handbook of Chemistry and Physics*^[48] and the *International Critical Tables*^[49] include a wide variety of compound types.

It is important to note that no handbook is exhaustive. They generally contain a limited universe of compounds (the largest handbook discussed here, Reaxys,^[50] presents only about 26 million of the more than 100 million

compounds reported in the CAS Registry), and not every compound has all properties covered by the handbook. There are several reasons for this. In order for a property to appear in a handbook, it must first be published somewhere in the literature. The editor of the handbook must locate it and decide to include it in the book. If one of these steps does not occur, it may be necessary for the scientist to rely on his or her own experimentally determined values for a given property.

In the online environment, several companies have made an effort to compile collections of handbooks that are simultaneously searchable. One of the most comprehensive of these collections is the Knovel Engineering and Scientific Online Reference Books.^[51] The Knovel collection includes many classic chemical handbooks, also available in print format, including Yaws' *Thermophysical Properties of Chemicals and Hydrocarbons*,^[52] and *The International Critical Tables*,^[49] as well as other information sources, such as *DIPPR Project 801 Database*,^[53] which lists constant and temperature-dependent properties for chemical substances. When accessing handbooks and databases through Knovel, however, it is very important to check the edition of the handbook being presented. Publishers will occasionally make older editions available through Knovel, while keeping the newest edition for distribution in print only or on their own online platform. Also, as publishers make and leave agreements with Knovel, books may be added or removed from the platform.

Reaxys

Reaxys is an interesting, hybrid handbook/indexing and abstracting source. It has as its basis two important and historic print sources, the *Beilstein Handbuch der Organischen Chemie*^[54] and the *Gmelin Handbuch der Anorganischen Chemie*,^[55] as well as the Elsevier Patent Chemistry Database. The data from the three seed sources have been completely integrated and are now being updated as a seamless whole, but it is important to understand the historic antecedents of the database in order to get a sense of its strengths and weaknesses.

Beilstein. The *Beilstein Handbuch der Organischen Chemie*, or the *Beilstein Handbook of Organic Chemistry*, is an enormous work that was, for a long time, the work of one individual. Friedrich Konrad Beilstein, a Russian chemist of German descent, decided to create a comprehensive handbook of all organic chemicals, their properties, and their reactions, and he edited the first (1881), second (1885), and third (1906) editions himself, before his death in 1906.^[56] The work of compiling the data then fell to the German Chemical Society, the Beilstein Institute, and, most recently, Elsevier, which incorporated the data into Reaxys. References to the literature date back to the 1770s, making it also one of the oldest secondary or

tertiary sources in chemistry. Although the first through fourth editions in print are published in German, the online text available through Reaxys has mostly been translated and is accessible even to non-German speakers. The handbook volumes do have some narrative information that is not included in Reaxys; however, a savvy searcher should be able to find most desired information by referring to the many references to the primary literature found in the compounds' records.

Gmelin. The *Gmelin Handbuch der Anorganischen Chemie*, or *Gmelin Handbook of Inorganic Chemistry*,^[55] is the inorganic/organometallic version of Beilstein. Named after Leopold Gmelin, who edited the first edition of the work in 1817,^[57] it was published by the Gmelin Institute for some time, before the data were purchased by Elsevier Science. Gmelin reviewed the literature from 1772 to the present and is incorporated in the Reaxys database. Although the series was begun with printed, German-language books, some of which may still be available from used book dealers, the print version is no longer being updated. Unlike Beilstein, which focused on compounds and is organized by substance, Gmelin focused on elements and the substances that they form. Such substances can include the pure elements, glasses, ceramics, organometallic substances, alloys, polymers, dopants, solid solutions, and isotopes. In the print version, substances were organized by key elements within them, with a set of volumes for each element, which contained all of the information both about the element and about its compounds and alloys. The handbook included reaction information, as well as hundreds of physical and chemical properties.

Searching Reaxys. At the time of this writing, Reaxys is most effectively used to find information about substances, their properties, and their reactions, and the substance and reaction information derives from a few hundred journals. Although Elsevier has added title and abstract-level references to articles from over 16,000 journals to Reaxys' "Literature" search context, these articles are not deep indexed for substance and reaction information. Chemists can search for known substances using a substance identifier (discussed below) in order to find physical and chemical properties or reactions. However, one of Reaxys' strengths is its structure search interface, which allows users to locate reactions of interest using a partial or complete reaction search (see Reaction Searching), as well as to profile substances by substructure or by properties, entering possible values or ranges of values for a list of properties and retrieving all substances that meet these criteria. It is also fairly easy to search for structures and property values simultaneously or to limit structure search results to only those substances for which a particular property is reported. Special mention should be made of Reaxys' unique way of describing

organometallic substances and “coordination compounds,” both of which are frequently difficult to locate using a structure or formula. A special code, called a “ligand formula” allows a chemist to search for the metals and the types of organic structures that are bound to them. This way, a variety of coordination compounds with the same basic connections and components can be retrieved.

Spectral atlases and crystallography collections

Spectra and crystal structures are frequently desired properties of compounds that serve similar purposes. *Spectroscopy* and *spectrometry* of substances falls into the realm of analytical chemistry. Broadly stated, when taking a spectrum of a substance, a researcher exposes that chemical to particular wavelengths of radiation and records the absorbances, reflections, vibrations, or bond breaking that occurs. The results are presented in a graph that indicates characteristic peaks or absorbances, which can be interpreted by a scientist to arrive at a structure for the compound. There are several kinds of spectra that are commonly used by chemists. Mass spectra are taken when a compound is hit with radiation and decomposes into fragments in an instrument called a mass spectrometer. The mass spectrometer measures and records the molecular weights of these fragments, and a knowledgeable scientist can deduce the composition of the parent compound from the size of the fragments. To obtain a nuclear magnetic resonance (NMR) spectrum, a chemist places a sample in an instrument that generates a strong magnetic field around it. He or she then obtains a graph, indicating the vibrations of and interactions between its atoms. Infrared (IR) and ultraviolet-visible (UV-VIS) spectra both indicate the wavelengths of light absorbed by a particular substance on a sloped graph.

Many scientists desire a graphical spectrum to compare to one that they have been taken themselves, and there are a number of free and proprietary print and online spectral atlases, including BioRad's KnowItAll products,^[58] the *Sadtler Handbook of Proton NMR Spectra*,^[59] the Aldrich NMR and IR/Raman sets^[60,61] (also available, free of charge, through the online Aldrich/Sigma/Fluka catalog), the NIST Chemistry Web Book,^[62] and the SDBS: Spectral Database of Organic Compounds^[63] from the National Institute of Advanced Industrial Science and Technology (AIST) in Japan. These resources have varying levels of quality and varying numbers of compounds, but all provide the user with graphical spectra. However, not all substances have spectral information available in this format. There are several handbooks that compile spectral lines, giving the wavelengths at which peaks occur, including the *CRC Atlas of Spectral Data and Physical Constants*^[64] and the *Handbook of Ultraviolet and Visible Spectra of Organic Compounds*.^[65] Other resources, like Reaxys, simply refer to articles in the literature that report spectra. CAS Registry

database on SciFinder (Scholar) has a mixture of spectral information; it links to graphical spectra collections from Wiley, BioRad, and AIST for many substances, provides literature references where others' spectra can be found, and, for some substances, has no spectral information at all.

A *crystal structure* of a substance uses X-rays to determine its structure unambiguously, including exact bond lengths and angles. A crystal structure of an organic, inorganic, or organometallic substance can prove the identity of a substance. However, crystal structures can also be used to determine the average bond length of a certain type of bond, as well as the differences in angle between three specific atoms in different types of substance. A crystal structure of a protein, in addition to providing bond lengths and angles, can indicate the way in which the protein folds. When searching for crystal structures, a scientist is generally looking for the exact distances and angles between all atoms in the substance. Therefore, he or she will want to download the “coordinates,” the location in space of all atoms present, in the .cif file format. The Cambridge Crystallographic Data Centre,^[66] a registered charity in the United Kingdom, curates a repository of small-molecule crystal structures that can be downloaded by individuals free of charge or searched through the Cambridge Structural Database (CSD).^[67] Inorganic compounds and substances can be found in the Inorganic Crystal Structure Database (ICSD),^[68] a proprietary database produced by FIZ Karlsruhe, while proteins are deposited in the RCSB Protein Data Bank (PDB),^[69] managed by Rutgers and UCSD and based on the Rutgers campus. While individuals are welcome to deposit their crystal structures in a structural database on their own initiative, some primary journal publishers go so far as to request that authors including crystal structures in their publications deposit their data with one of the three repositories. Although these three tools have robust search and retrieval engines, it is important to note that they contain curated versions of researcher-deposited crystal structures and therefore cross the line from secondary to primary literature. All three systems will permit interested parties to download the crystal structure information files (.cif) of substances in the database, which can then be used in crystal structure visualization or manipulation programs.

IDENTIFYING SUBSTANCES FOR INFORMATION RETRIEVAL

One of the greatest challenges to a searcher unfamiliar with chemistry or chemical information is navigating the multitude of unique access points to the literature. In addition to performing successful topic searches, a researcher will be called upon to find information about chemicals, which have many different forms of identification. The following sections describe various identifiers that can be used when searching for chemicals, times at which they

are particularly helpful, and general strengths and weaknesses of each type.

Ambiguous Chemical Identifiers

Of the many ways of identifying compounds, relatively few are completely unambiguous, one-to-one identifiers. Ambiguous identifiers, or those that are not one-to-one, abound and include chemical names, formulae, molecular weights, and various physical properties. This section discusses two of the most important ambiguous identifiers: chemical names and formulae.

Chemical names

Chemical nomenclature is frequently an art, rather than a science. Names are difficult identifiers to use in information retrieval because they are infrequently one-to-one identifiers for substances. There are two official systems of nomenclature that are widely used: the *IUPAC* system, which employs rules developed by the International Union of Pure and Applied Chemistry, and the *CAS* system, with rules made by the Chemical Abstract Service. One of these two systems is usually required when naming substances in a journal article; however, frequently used chemicals are generally given at least one common name, also called a *trivial name*, and substances that are commercially available often have at least one *trade name*, as well. In late 2015, the CAS Registry database showed 134 systematic, trivial, and trade names for the compound commonly known as aspirin.^[70] This creates a many-to-one problem for information retrieval; there are many possible names for a single compound, and a searcher who wishes to locate chemicals by name must hope that the name variant that he or she has is the same as the one found in the index of a reference book or the electronic record in a database. A further problem arises because, in electronic information sources, the chemical name field is a “string” field, in which one must exactly match the input search string to an identical string in the chemical name field of a record. No typing errors are tolerated, and the databases do not have a “did you mean” feature since the alteration of a single character could indicate a completely different substance. For example, the substances “ethanol” and “ethanal” are two completely different molecules. For this reason, if one is having difficulty locating a substance by its chemical name, the best approach is usually to locate the name in a resource with an extensive synonym list and find the molecular formula or CAS Registry Number, which can then be used in the original resource to obtain the desired information.

Chemical formulae

A chemical formula describes the number or ratio of atoms of each type present in a substance. There are three general types of formula. The *molecular formula* is the

formula most frequently used both by chemists and in information retrieval. A molecular formula lists the symbol for each atom in the substance, found by consulting the periodic table, followed by the number of that type of atom that appears in the substance. The formulae are written using a convention called *Hill Order*, which provides some degree of standardization. The first step in constructing a Hill Order formula for any substance is to group all like atoms together, ignoring functional groups or units. For organic compounds, defined as substances containing one or more carbon atoms, the atomic symbols are then ordered as follows: carbon, hydrogen, and all other atoms in alphabetical order. For example, the molecular formula for 4-aminobutanoic acid, which contains four carbon atoms, two oxygen atoms, nine hydrogen atoms, and a nitrogen atom is written $C_4H_9NO_2$. For inorganic substances, defined as substances containing no carbon atoms, all atomic symbols appear in alphabetical order. For example, the molecular formula for sodium chloride, which contains one sodium atom and one chlorine atom, would be written as $ClNa$, not $NaCl$.

The other two types of formula, empirical formula and structural formula, are used very infrequently in information retrieval. The **empirical formula** gives the ratio between the different types of atom found in a substance. The molecular formula of glucose is $C_6H_{12}O_6$; so, its empirical formula is CH_2O . The **structural formula** is written to give some inkling as to the connectivity of the atoms in the molecule. For example, 4-aminobutanoic acid, $C_4H_9NO_2$, has the following structure (Fig. 1).

The structural formula for this substance would then be either $COOH-CH_2-CH_2-NH_2$ or $CO_2H-CH_2-CH_2-CH_2-NH_2$. While empirical formula information can be used in some advanced search systems, such as the Registry file on STN, to search for compounds that have a given ratio of atom types, the use of structural formula has mostly been replaced by chemical structure searching in online resources, although some biochemists will still write out a structural formula instead of drawing a structure for simple molecules.

Searching by molecular formula presents the opposite kind of problem to that experienced when searching by chemical name. Since a molecular formula gives no indication of the connectivity of the various atoms in the molecule, it is very easy to find many molecules with the

Fig. 1 Structure of 4-aminobutanoic acid.

same formula. However, most resources present the names or structures alongside the list of formulae in the book index or electronic search results, making it easier for a searcher to select the correct substance from the list. Another method of surmounting this problem is by selecting a different identifier by which to search.

Unambiguous Chemical Identifiers

It is preferable, although not always possible, to use an unambiguous identifier when searching for a substance. The three most commonly used one-to-one identifiers are chemical structure, sequence, and CAS Registry Number, although there are others. A relatively new identifier, the InChI, is a unique, text-based string that can be used with Web search engines, such as Google, but is most commonly used by database providers behind the scenes to link information sources that contain the same substances. Spectra, discussed earlier, serve as the fingerprints of chemicals, presenting a graph with characteristic peaks that enable chemists to determine the exact structure of the substance in question. Each identifier has its drawbacks in information retrieval, yet the use of each will generally retrieve a single substance.

Chemical structures

Structure is the least ambiguous identifier most commonly used for small, organic, or organometallic compounds. A substance's structure is akin to its photo ID; it shows not only the types and numbers of atoms that make up the substance, but also how they are connected. The structure of dicyclohexyl methanone ($C_{13}H_{22}O$) appears below (Fig. 2), using normal conventions for drawing organic compounds. Carbon atoms appear as line termini, and hydrogen atoms are understood.

At present, most chemistry databases and electronic resources have some form of structure search capability, generally provided through the means of a Java plug-in, a non-Java editor, or, in a few cases, specialized client software. Such resources allow a user to draw a structure of choice and then search for either exact matches or for larger molecules that contain the structural elements as drawn. The tools available vary from resource to resource; free resources tend to offer only basic search options, while resources like Reaxys, which rely heavily on structure searching, allow the user to construct extremely

Fig. 2 Structure of dicyclohexyl methanone.

complex queries. Although it is not possible to search for structures in most print reference works, it is easy to count the atoms in a structure, generate the substance's molecular formula, and look it up in a formula index.

Sequences

Many biological chemists study very large molecules called proteins and nucleotides. These are, essentially, polymers consisting of many smaller units. The components of proteins are amino acids, while nucleotides are composed of bases. Because the sequence of the component amino acids (also called *residues*) or bases is very important to the function of the biomolecule, a molecular formula is not a good way to describe its composition. Biochemists use identifiers called sequences to describe the order of the component pieces. Each component is given a letter code. The letters are then strung together in the order in which the segments appear in the biomolecule. Resources that contain proteins or nucleotides generally allow sequence searching, and many let researchers locate sequentially similar substances using an algorithm like BLAST, described later in the article.

CAS Registry Numbers®

The Chemical Abstract Service assigns a unique, one-to-one identifier, called the *CAS Registry Number* (*CAS RN*), to each compound published in the literature. CAS RNs are formatted in the following manner, where X, Y, and Z represent any of the digits 0–9:

XXXXXXX-YY-Z

The first set of digits (X) is arbitrarily sized but has at least two digits. The second set (Y) contains two digits, and the third set (Z), or the check digit, is a single digit. CAS RNs are helpful because they aim to be completely unambiguous. They can be difficult to search because few people memorize them, and therefore, a source must be used to determine the CAS RN for each substance. In addition, since they are unique identifiers, a CAS RN search will not retrieve compounds that are structurally identical but contain one or more element with a higher or lower number of neutrons than usual, called an isotope. At times, it is important to exclude these “isotopically labeled” compounds, but, since their formation and general behavior is usually identical to their unlabeled counterparts, useful information can be missed if they are omitted. Although most resources have a CAS RN index or search function, these numbers are proprietary, and database providers must request permission from CAS to use them in their products.

InChIs™

An *InChI*™, or an *International Chemical Identifier*, can be described as IUPAC's version of the CAS Registry

Fig. 3 Structure and InChI for dicyclohexyl methanone. The first set of characters refers to the InChI standard being used, the second set is the molecular formula, the third set tells how the molecular backbone is connected, and the fourth set indicates the locations of hydrogen atoms.

Number, only with structural information built in.^[71] IUPAC defines an InChI™ as “a non-proprietary identifier for chemical substances that can be used in printed and electronic data sources thus enabling easier linking of diverse data compilations.”^[71] InChI strings are generated using free software provided by IUPAC, and two free drawing programs, ACD’s ChemSketch and the PubChem Server Side Structure Editor, can both generate InChIs from structures. InChIs appear as a long text string and can therefore be used for searching the Web, as well as text-based databases and search engines. Below are the structure and corresponding InChI for dicyclohexyl methanone (Fig. 3):

InChI=1S/C13H22O/c14-13(11-7-3-1-4-8-11)12-9-5-2-6-10-12/h11-12H,1-10H2

InChIs carry all of the advantages of CAS RNs, as well as the added advantage that database providers do not have to request permission to use them in their records. As was previously mentioned, they are most likely to be used as linkers by information providers, but it is possible to use them within those databases that include them in the substances’ records.

SEARCHING FOR SUBSTANCES IN THE CHEMICAL LITERATURE

Specialized Search Techniques

Chemical names, molecular formulae, and CAS Registry Numbers can all be used to retrieve information about chemicals. In online sources, the use of structure and sequence are also prevalent. However, there are other specialized search techniques that can be used to locate substances, their properties, and their reactions in electronic resources. Substructure searching and sequence similarity searching, using algorithms such as BLAST, can be used to locate substances that are similar in composition. Reaction search techniques can be used to find all ways of executing a particular reaction, to learn the best way to perform a reaction with a specific reactant and product,

and to find out exactly what will happen when two substances react.

Substructure searching

Frequently, chemists will want to search the literature, not for specific structures, but for structures that resemble a substance of interest. For example, assume that a scientist has discovered that some natural products have been found to have anticancer activity, which can be traced to a certain portion of their structure. He would like to figure out how to make that structural segment in the lab and is writing a grant application to fund this research; so, he wants to locate many examples of substances containing that fragment that also exhibit anticancer activity. Another example of the utility of substructure searching is a scientist who tries and fails to make a new substance. She can search for papers that report the synthesis of structurally similar substances and then apply the techniques to her own system.

Substructure searching, simply put, is a truncation search for a molecule. The searcher draws the portion of the structure that interests him or her, and the database retrieves all molecules that contain that structural fragment. In general terms, the query substructure can be thought of as a template that is superimposed over all substances in the database. A substance is retrieved as part of the hit set only if all atoms and bonds in the template exactly match atoms and bonds found in that substance.

In Fig. 4, the searcher input the boxed substructure in the center and retrieved the three structures surrounding it. Note that, when performing a substructure search, hydrogen atoms must be drawn; they are no longer understood. This substructure, therefore, contains nine “free sites,” places where atoms, in this case carbon, chemically must form additional bonds. Any kind of atom or group can be attached to each of these sites. In Fig. 4, the substructure query is bold in each of the three retrieved substances, and the additional substituents appear in a lighter color. If the searcher wanted to be more specific about the type of substance retrieved, he or she would need to place additional restrictions on these free sites. For examples, the chemist could specify that atoms attached must not be part of a ring; that only nonhydrogen atom attachments are allowed; or that only carbon, nitrogen, or oxygen can attach at a particular site.

Reaction searching

Since many chemists seek to make new compounds or study the reactivity of known compounds, it is logical to assume that searching for particular reactions is a valuable tool. Reaction searching is most frequently used by chemists attempting to synthesize novel compounds or seeking new and improved methods of making known substances. For example, a chemist may wish to convert one

Fig. 4 A sample substructure and possible results obtained when using it to search. Note that the substructure is highlighted in black in each of the search results.

compound into another, but he may not know the proper reagents or conditions to apply to make this reaction happen. Another chemist may want to synthesize a compound without having a particular starting material in mind. Still another might be interested in all types of reactions performed by a given class, or type, of compound.

Many databases allow both partial and complete reaction searching using either exact structures or substructures. The chemist who wishes to use a particular reactant to make a product will perform a *complete reaction* search (Fig. 5A), drawing both the starting material and the product into the search engine. The chemist exploring possible methods of synthesizing a compound, who does not care which starting materials they use, will instead use a *partial reaction* search (Fig. 5B), drawing only the product, labeling it as such, and indicating by means of a hash mark the bond that is to be formed in the course of the reaction.

There are many reaction databases available, and each has different methods of search available to users. Some of the more common reaction databases are the CASREACT database from CAS and the reaction module on Reaxys.

Fig. 5 (A) A complete reaction search, in which a chlorine atom is added to a benzene molecule. (B) A partial reaction search intended to locate all possible methods of adding the chlorine to the benzene ring.

In recent years, reaction databases have begun adding synthesis planning options to their search interface. For example, from a substance search in SciFinder, one can click on the structure and select an option to “Synthesize this...” Reaxys offers a more sophisticated synthesis planner that allows you to explore various routes of making a molecule in question. Starting with the target, researchers can click on the “Synthesize” links to retrieve a list of potential reactions that result in that product, from which they can choose their desired preparation. As they work backwards, the synthesis planner constructs a tree-like reaction scheme, indicating the chosen reactants and reagents for each step, and generates a list of references in which the protocols can be located. InfoChem’s *IC_{SYNTH}* product will also allow chemists to generate potential synthetic routes to a target molecule.^[72]

Sequence searching and BLAST

Frequently, scientists will want to locate proteins or nucleic acids that have sequences similar to a sequence of interest. If a biological chemist is studying a human protein that has never been studied, it might be helpful for him to see whether there are any similar proteins in other organisms that have been more extensively researched. Searching for sequentially similar proteins or nucleic acids in different organisms can also give indications of evolutionary relationships between species. Frequently, locating intensely studied proteins or nucleic acids with similar sequence can help a researcher determine the putative identity and function of a given substance. The best method for accomplishing these goals is to perform some kind of similarity search in a database of sequences.

“**BLAST**” stands for “Basic Local Alignment Search Tool,” and it is one of the most common methods of

locating sequentially similar proteins or nucleic acids. The BLAST algorithm is complex, but it basically looks for sequences in a database, or **subject** sequences, that have a small sequence fragment that is identical or highly similar to one found in a query sequence. Starting at this sequence fragment, the system then works outward in both directions, comparing each nucleotide or amino acid of the query sequence to those in each subject sequence in the database. It then determines the length of the “matching” section between the query and each subject sequence and assigns each subject a score, based on the length of the similar section and the closeness of the match, and presents the results in order of score, from most to least similar. Advanced searchers can adjust the parameters of a search to be more or less sensitive, allowing retrieval of more or less disparate sequences. BLAST searching is frequently used to identify similar sequences in different organisms, often with an eye to discovering evolutionary patterns or functional similarities.^[73]

CONCLUSIONS

The literature of chemistry is as varied as the types of research that chemists perform, and is likely to become more so as chemical research becomes increasingly multidisciplinary. Chemists are avid readers, partly driven by the need to experiment efficiently because their research is so expensive. As a result, the chemists frequently desire or need to do their own searches, evaluate their results, and immediately modify or refine their searches, requiring a large degree of autonomy and strong searching skills. Occasionally, particularly in industry, they will ask an information professional to perform searches for them, evaluate the results, and request modifications. However, many academic chemists have a decent familiarity with their literature and, while they will occasionally require assistance framing searches, they often wish to be taught rather than spoon fed. Many of the tools, particularly the SciFinder and SciFinder Scholar interfaces, are aimed at end user searchers. With appropriate instruction in the specialized search techniques and entry points to the resources, chemists can be efficient searchers and find most of what they need to do their research.

Chemists should be taught to use review sources, including encyclopedias, treatises, and review articles, for background research, before proceeding to the primary literature in journals, books, and patents. Indices, abstracts, and catalogs will assist them in identifying good primary research on which to build, as well as chemicals and equipment. Handbooks can supply quick values for properties and references to the literature in which they were reported. All resources can be searched with unique access points, including chemical name, formula, structure, sequence, and CAS Registry Number, and many

allow specialized searching, such as substructure searches, reaction searches, and BLAST.

ACKNOWLEDGMENTS

I would like to thank the University of Pennsylvania Libraries for their support and acknowledge the assistance of Eric Shively, Thomas Krimmer, Renata Geer, Carlos Rodriguez, and Dianne Mizzzy, who provided valuable input during the preparation of the previous edition of this manuscript.

Chemoinformatics

Peter Willett

Department of Information Studies, University of Sheffield, Sheffield, U.K.

Abstract

The entry summarizes the principal tools in modern chemoinformatics systems, principally in the pharmaceutical industry. These tools enable molecules to be selected for biological testing as potential drugs, and include methods for searching databases of two-dimensional and three-dimensional chemical structures, and for predicting the properties of molecules from their structures.

INTRODUCTION

Information systems in chemistry have a long history, first in printed and then in computerized form, and the great bulk of the world's chemical information is now available on the scientist's desktop.^[1] Much of this information is textual (e.g., the full-text of a journal article) or numeric (e.g., a molecule's boiling point) in nature, but there is an additional data type that distinguishes chemical information systems from those designed for more general use: the structures of chemical molecules, normally in the form of a two-dimensional (2D) structure diagram but increasingly also in three-dimensional (3D) form. Molecules (and their reactions and properties) lie at the heart of chemistry and this has spurred the development of systems for the representation of structures, not just as images but in a form that will enable sophisticated processing to be carried out on them. The focus on the structure is the principal distinguishing feature of chemical information systems, in much the same way as biological and geographic information systems highlight the importance of biological sequences and of cartographic information, respectively.

Computer-based systems for the manipulation of structural information started to be developed in the early 1960s, most notably the establishment of the Chemical Abstracts Service Registry System to record all the molecules that are reported in the world's scientific literature.^[2] Systems such as this focused on tools for rapid and effective database searching; at the same time, scientists, principally in the pharmaceutical industry, were developing computer systems for modeling individual molecules so that they could be displayed interactively and their properties, shapes, and reactions computed from their two-dimensional (2D) or three-dimensional (3D) structures. These two areas of research developed strongly over the next two decades,^[3,4] with the establishment of chemoinformatics—"the application of informatics methods to solve chemical problems"^[4]—as a distinct discipline being driven in part by the need to integrate these two approaches to the manipulation of structural

information. This need has been strengthened by technological developments (specifically, the techniques of combinatorial chemistry and high-throughput biological screening) that have brought about an increase by at least two orders of magnitude in the volumes of data that need to be processed in chemical research and development. Chemistry is by no means unique in needing to assimilate and to rationalize vast bodies of data, and informatics tools are thus being increasingly developed and applied in many subject domains. Here, we summarize the components of modern chemoinformatics systems, describing the main techniques that are used to search databases of chemical structures and to correlate the biological properties of molecules with their structures. Much of the discussion relates to the pharmaceutical industry since that is where many of the developments have taken place to support the discovery of new drugs; however, the techniques are increasingly being applied in many areas of chemistry, such as structure elucidation, reaction prediction, and synthesis design. The entry focuses on methods for searching chemical databases, with brief accounts of some of the other approaches that are used to support drug-discovery programs; more detailed accounts of chemoinformatics are provided in the textbooks by Gasteiger and Engels^[4] and by Leach and Gillet,^[5] and in the standard reference work edited by Gasteiger.^[6]

SEARCHING DATABASES OF 2D STRUCTURES

Search lies at the heart of any type of information system, and methods for searching chemical databases have been studied now for over four decades. These methods can be divided into two broad classes: those that are used with databases of 2D structures, where molecules are represented by conventional chemical structure diagrams; and those that are used with databases of 3D structures, where molecules are represented by sets of atomic coordinates in 3D space. This entry deals with the first group of methods although, as we shall see in the following entry,

many of the techniques are also applicable in the 3D context.

Representation and Structure Searching

The two most important types of representation that have been used to describe a chemical structure in machine-readable form are the *line notation* and the *connection table*. A line notation encodes the structure of a molecule in a text string, in which individual symbols encode atoms or groups of atoms, with the bonds linking these atoms normally implicit in the ordering (which is subject to strict preference rules). Line notations were widely used in the 1960s and 1970s, with the Wiswesser Line Notation in particular forming the basis for both corporate and public chemical information systems.^[7] The most popular current line notation is the SMILES (Simplified Molecular Input Line Entry Specification) notation, a compact text string that can be used for the input of chemical structures and for *structure search*. Structure search is one of the principal types of database search (the others are described later in this entry)

and involves scanning a database for the record associated with a specific molecule. Such searches are typically carried out to retrieve data associated with that molecule, e.g., how it can be synthesized or its solubility. This is the chemical equivalent of a known-item search, e.g., looking for an ISBN in a library catalog to see if a copy of a book is available for loan or scanning a telephone directory to get a person's telephone number, and can be effected using conventional computer techniques such as string matching or hash coding. However, line notations are far less suitable for the other types of chemical searching, which require an explicit and detailed description of the pattern of bonds in a molecule to enable effective searches to be carried out. This information is encoded in a connection table, which can be regarded as a *chemical graph*, in which the nodes and edges of a graph represent the atoms and bonds, respectively, of a molecule. The hydrogen atoms are normally excluded from a connection table since their presence can be deduced from simple considerations of atomic valency. An example of a structure diagram and the corresponding chemical name, connection table, and SMILES are shown in Fig. 1.

Fig. 1 Example of (A) a structure diagram, (B) systematic nomenclature, (C) connection table in MDL format (see URL <http://www.mdli.com>), and (D) SMILES for a molecule.

Substructure Searching

The availability of the graph-based, connection-table representation means that chemical database applications can make use of algorithms originally developed for the matching of graphs, in particular the use of a subgraph isomorphism algorithm to carry out *substructure searching*.^[8] This involves scanning a database for all of those molecules that contain a user-defined partial structure, e.g., all of the molecules that contain the four linked rings that characterize a steroid. This is the chemical equivalent of a Boolean text search, e.g., looking for all documents satisfying the logical constraint (chemical AND database* AND search*), and requires rapid access not just to the entire structure of a molecule but also to all of its constituent parts. An example of a substructure search is shown in Fig. 2.

A subgraph isomorphism algorithm checks whether a query graph is contained within another graph, and such an algorithm hence provides a simple and direct way of carrying out a substructure search given a set of connection-tables. However, while this is an effective search procedure, it is a very inefficient one, since subgraph isomorphism, like many graph algorithms, has an expected time complexity that is a factorial function of the numbers of nodes in the two graphs that are being compared. The computational requirements are lessened, when compared to graphs in general, because chemical graphs are small (typical organic molecules contain 20–30 nonhydrogen atoms); are of low complexity (since each atom is bonded to only a very few other atoms, the exact number depending on its valence state); and have node and edge labels (i.e., the atom and bond types) that can be used to constrain the number of graph matches that need to be considered. Even so, substructure searching of large chemical databases using subgraph isomorphism would be totally infeasible if it had not proved possible to provide an initial, *screening* search that eliminates the great bulk of a database from the time-consuming subgraph search.

Screening is based on the idea that a database-molecule cannot possibly contain the sought query moiety unless that molecule contains all of the fragment substructures that are contained in the query. Only if each and every one of these fragments is present is it worth carrying out the subgraph search to determine whether they are joined together in exactly the same way as they are in the query. A range of types of fragment can be algorithmically generated from a molecule's connection table. One simple approach is to use common rings and functional groups so that, e.g., a molecule might be characterized in chemically meaningful terms as containing a phenyl ring, an acid amide group, and a methyl group (in much the same way as a paper in an academic journal might be characterized by some number of keywords). More commonly, the fragments are small atom-, bond-, or ring-centered substructures; for example, a molecule might be characterized

Fig. 2 Example of a 2D substructure search. The search is for the diphenyl ether query substructure at the top of the figure, below which are shown five of the hits resulting from a search of the National Cancer Institute database of molecules that have been tested in the U.S. government anticancer program (see URL <http://dtp.nci.nih.gov/>). This database is also used for the search outputs shown in Figs. 3 and 4.

by *augmented atoms*, where an augmented atom is an atom together with the atoms that are bonded directly to it, or by a chain of four atoms and the three bonds that link these atoms together.

The presence or absence of such fragments (either in a query or in a database molecule) is encoded in a *fingerprint* or *bit-string*. A fingerprint is a binary vector where each of the bits (or groups of bits in some cases) is set to one to indicate that a particular fragment (or fragments) is present in the connection table describing a molecule. A screen search is then carried out by comparing the bit-string describing the query with the bit-string describing a database molecule; only if a logical intersection (Boolean AND) of the two fingerprints confirms that all the specified query fragments are indeed present will the detailed and time-consuming subgraph isomorphism match be carried out for that database molecule. An effective screening system will ensure that less than 1% of the database

molecules need to undergo this second-level search. Other approaches to 2D substructure searching have been described,^[9] but the fragment-screening approach continues to be by far the most common; moreover, fingerprints are used not just for 2D substructure searching but also for many other applications in chemoinformatics, as discussed below.

Similarity Searching

The advent of the Web has meant that Boolean searching, although used for many years by library and information specialists, is now used far less than the alternative best-match or ranked-output approaches that characterize Web search engines. The chemical equivalent of this approach to database access is called *similarity searching*.^[10] Here, a user enters a complete molecule, which is normally referred to as the *reference* or *target* structure, and the similarity is computed between this reference structure and each of the database molecules. The database molecules are then ranked in order of decreasing similarity and the most similar, the *nearest neighbors*, presented to the user as the output from the search.

The basis for similarity searching is the Similar Property Principle, which states that molecules that are structurally similar are likely to have similar properties. Thus, if a biologically active molecule is used as the reference structure then its nearest neighbors are also likely to be active (in much the same way as a Google search based on the keywords from a known relevant document is likely to identify further relevant documents). This is clearly a simple way to search a database but it will only be effective if an appropriate measure of intermolecular similarity is used. There is a large, growing literature on chemical similarity,^[11] but current systems are overwhelmingly based on the use of fingerprint-based measures of structural similarity. In a substructure search, two fingerprints are compared to determine if one is contained within the other; in a similarity search, two fingerprints are compared

to determine how many bits (normally the bits that are switched on) are in common. The number of common bits represents the number of common fragments and generally after a normalization stage to give a value between zero and unity, the overall degree of resemblance of the two molecules whose fingerprints are being compared. This simple approach has proved to be very popular, enabling the identification of biologically active molecules in chemical databases at minimal computational cost and often more effectively than other, more complex types of similarity measure.^[12] An example of a fingerprint-based similarity search is shown in Fig. 3.

Patent and Reaction Searching

There is another type of 2D structure that is of particular importance in industrial research and development, and this is a molecule in a chemical patent. Patents in chemistry resemble those in other fields in describing novel entities and their uses (in this case chemical molecules and some sort of useful property), but they differ in the way that the molecules are described. Specifically, whilst individual, specific molecules are generally included in a patent, either as a name or as a structure diagram, there may also be one or more *generic*, or *Markush*, structures. A generic structure is a high-level description not of a single molecule but of a whole class of molecules that possess common structural features; for example, there may be a range of different substituents possible at a single position on an invariant central ring system, or there may be limits on the numbers and types of atoms allowed in a heterocycle.^[13] A single generic structure may represent many thousands, or even millions, of individual specific molecules, and is included in a patent so that the originating company can claim patent protection for all of the molecules implied by the high-level description, without the need to describe (or even, in most cases, to synthesize and test) the individual molecules. Fragment-screening and graph-matching procedures analogous to those

Fig. 3 Example of a fingerprint-based 2D similarity search, showing a query molecule and five of its nearest neighbors.

described above have been developed for patent databases; however, it can still be difficult to describe precisely some types of patent and to carry out searches that are as effective as those possible on databases of conventional, fully defined molecules.^[14]

Finally in this entry, it is appropriate to mention search techniques for databases of chemical reactions. Here, a database record consists not of a single molecule but of two, linked sets of molecules, i.e., the sets of reactants and products; in addition, there may also be reagents or catalysts that are necessary for the reaction to proceed in high yield. Some types of query that a user might wish to pose to a reactions database, e.g., all syntheses of a specific molecule or how to convert one molecule to another, can be achieved using simple modifications of conventional structure searching procedures. However, an effective reactions database also needs to be able to represent and to search not just the molecules that are involved in a reaction but also their constituent *reaction sites*, i.e., the parts of the reactants and products where the substructural change engendered by the reaction has taken place.^[15] For example, a user might wish to retrieve all reactions involving the combination of two acid groups to form a heterocycle, i.e., a form of substructure searching that will again involve simple modifications of conventional fingerprint and graph-match algorithms. In addition, however, this sort of search will require effective algorithms to recognize the substructural differences between the reactants and products, and hence the location of the reaction sites, and then the ability to link together information about both the reacting molecules and the reaction sites. For example, a user might wish to retrieve all reactions involving the combination of two acid groups to form a heterocycle (as previously) whilst also specifying that another acid group elsewhere remains unchanged during the reaction. Systems providing such comprehensive retrieval capabilities are now well established,^[16] and facilities can also be provided for reaction similarity searching.

SEARCHING DATABASES OF 3D STRUCTURES

Systems for structure and 2D substructure searching were available for both corporate and public databases by the early 1980s but a decade was to pass before techniques were developed for the effective processing of 3D structures.^[17] Indeed, even today, 3D searching systems are restricted to corporate environments where the file-sizes are much less than the large public databases available from Chemical Abstracts Service (at <http://www.cas.org>) and from Beilstein (at <http://www.beilstein.com>).

The principal source of experimental data on the 3D structures of small molecules is the Cambridge Structural Database (at <http://www.ccdc.cam.ac.uk/>), which contains atomic coordinate data for approximately 400K molecules for which an x-ray crystal structure determination has

been carried out.^[18] X-ray techniques are constantly evolving but this number is less than 2% of the number of molecules for which the 2D structure is known; accordingly, if 3D searches need to be carried out, computational, rather than experimental, techniques must be used to generate the requisite atomic coordinate data. Molecular modeling provides a range of tools that can be used to generate 3D structures, using sophisticated approaches such as quantum mechanics, molecular dynamics, and molecular mechanics,^[19] but these are too slow if structures need to be generated for hundreds of thousands or millions of molecules. Instead, *structure generation* programs have been developed that can rapidly generate reasonably accurate sets of atomic coordinates from a 2D connection table.^[20] The set of coordinates for a molecule can then be used to compute the distances between all pairs of (nonhydrogen) atoms. These distances form the basis for a 3D chemical graph, in which the nodes and edges of the graph characterize the atoms and interatomic distances, respectively (as against the atoms and bonds in a 2D chemical graph).

Substructure Searching

A *pharmacophore*, or *pharmacophoric pattern*, is the geometric arrangement of features in a molecule that interacts with a biological receptor and that allows a molecule to exhibit the desired biological activity. Potentially bioactive molecules can hence be identified by searching a database for all those molecules containing a query pharmacophore, this typically consisting of a small numbers of atoms and associated interatomic distances. An example of a pharmacophore is shown in the upper part of Fig. 4. Such patterns are derived from analysis of sets of known bioactive molecules to identify the geometric features that they have in common.^[21] The 3D graph for a molecule is more complex than the corresponding 2D graph since there are far more edges present (each atom is separated by a distance from every other atom in the molecule but is only bonded to some small number of other atoms) but the fact that a graph representation is available means that we can again apply the screening and subgraph isomorphism approaches described previously.

The condition for a subgraph match in 3D substructure searching is now not that atoms are bonded together in the correct way but that they are separated by the correct distances, normally to within some small level of tolerance such as ± 0.5 Å, and a subgraph isomorphism algorithm can be modified to handle such data. The screens that are used are based on interatomic distance ranges, e.g., a bit in a fingerprint might be set to denote the presence of an oxygen and a nitrogen atom separated by 3.5–5.0 Å. The lower portion of Fig. 4 illustrates some of the molecules retrieved in the search for the pattern in the upper portion of the figure, and demonstrates the wide range of types of molecule that contain the query

Fig. 4 Typical hit structures for the antileukemic pharmacophore shown at the top of the page, with the presence of the pharmacophore in the retrieved molecules shown by dotted lines.

Source: From Zee-Cheng and Cheng.^[22]

pharmacophore. Thus the structures retrieved from a 3D substructure search are typically far more diverse than those retrieved from the corresponding 2D search. The former is hence well equipped to identify novel structural classes that might not be covered by existing chemical patents, a commercially important capability that is increasingly referred to as *scaffold hopping*.^[23]

The use of a graph in which the distance between a pair of atoms is fixed is not generally correct, since most molecules are *flexible*, i.e., they can adopt a large number of

different conformations, which vary both in shape and in energetic stability. Different conformations can result in different sets of interatomic distances, and a 3D substructure search of a database of rigid molecules may thus fail to retrieve many of them containing the query pharmacophore if each molecule is represented by a single, low-energy conformation. One way to overcome this problem is to store multiple conformations in the database for each molecule, with the conformations chosen to encompass the entire range of energetically feasible shapes that the molecule can adopt; there are many ways in which such a conformational analysis can be carried out.^[19] The distance-based screening and subgraph isomorphism searches are then applied to all of the conformations describing each of the database-molecules. An alternative approach, more precise but also potentially much more time consuming, carries out a conformational analysis during the execution of the search, with the screening and subgraph-isomorphism stages being used to minimize the numbers of molecules and numbers of conformations that need to be explored by the conformation-analysis routine. This approach also requires the use of a different type of graph. Whereas the edges in a graph for rigid 3D searching encode interatomic distances, the edges for flexible 3D searching encode distance-ranges, the lower- and upper-bounds of which correspond to the minimum- and maximum-possible distances between each pair of atoms. The resulting graph encompasses all possible geometrically feasible shapes that the molecule can adopt; the final conformational analysis then checks whether hits that are geometrically feasible are also energetically feasible.^[24]

Similarity Searching and Docking

Pharmacophore searching is now well established, although a flexible search for a broadly defined 3D pattern can be extremely time consuming unless other information can be used to constrain the search. Similarity searching in 3D is less well established. As noted previously, similarity measures based on fingerprints are used in nearly all 2D similarity searching systems, but there is still much debate as to how similarity in 3D should be quantified. Approaches based on comparing sets of interatomic distances (and more complex distance functions), the shapes of molecular surfaces, and surrounding electrostatic fields, *inter alia*, have all been discussed in the literature.^[25] Thus far, however, it is not clear that any one approach is consistently superior to the others or, indeed, that the increased (in some cases massively increased) computational load results in searches that are more effective than similarity searches based on conventional 2D fingerprints.^[10,11]

There is, however, one type of 3D search that is very widely used: *docking*. Similarity searching seeks database-molecules that are structurally similar to the reference structure; docking seeks database-molecules that are structurally *complementary* to the binding-site of a protein, i.e.,

that part of a protein that is involved in a biochemical pathway that a molecule needs to modify if it is to function as a drug. The need for complementarity arises from the so-called *lock-and-key* theory of drug action, which assumes that a molecule is likely to be able to act as a drug if it fits into a binding-site in much the same way as a key fits into a lock. A docking search hence requires that we know the 3D structure of the protein, information that is increasingly available from studies using x-ray crystallography and NMR (nuclear magnetic resonance) spectroscopy: the Protein Data Bank (at <http://www.wwpdb.org/>) is the principal repository of such data.^[26] The first program for docking was described by Kuntz et al.,^[27] whose DOCK program was based on complementarity of shape, as encoded in sphere-like descriptions of the shapes of the binding-site and the database-molecules. This basic approach has since been much extended, with enhancements including the use of chemical complementarity (e.g., areas of positive charge fit best with areas of negative charge) and the inclusion of algorithms that permit the docking of flexible molecules (although it is not generally possible, as yet, to allow for flexibility in the protein).^[28]

COMPUTER-AIDED DRUG DISCOVERY

This final entry describes the use of chemoinformatics to support drug discovery since the pharmaceutical industry has been, thus far, chemoinformatics' principal application domain. However, it is also being increasingly used in related specialty areas, e.g., the agrochemical and biotechnology industries, and is applicable in principle to any area of chemistry where there is need to identify molecules with particular types of property. We focus here on three applications: *quantitative structure–activity relationships*, *molecular diversity analysis*, and *ADMET prediction*. All of these, and the searching methods described thus far, can be considered as examples of *virtual* (or *in silico*) *screening*.^[29,30] Even with the significant developments that have taken place in the speed of biological screening, this is still the most time consuming and most expensive part of the discovery stage of pharmaceutical research (although the costs of this stage are far outweighed by the costs of the subsequent development and clinical stages). The cost-effectiveness of drug discovery will hence be maximized if molecules with a low probability of activity can be eliminated at as early a stage as possible from the discovery process; virtual screening is one of the most important tools available to achieve this end.

Quantitative Structure–Activity Relationships

Thus far, we have focused on the searching capabilities of modern chemoinformatics systems. Of equal importance is their ability to correlate structural information with the biological properties of molecules, which in the case of

pharmaceutical research is normally some sort of therapeutic property, e.g. lowering a person's blood pressure. Biological experiments are time consuming and expensive, even at the *in vitro* level, and hence an effective method for predicting a molecule's properties from its 2D or 3D structure can help to enhance research productivity by focusing experimental studies on those few molecules that are predicted to exhibit the desired activity. The basic methodology is to take some number of molecules for which the necessary biological data are available, and then to use this *training-set* to develop a mathematical model relating the experimental measurements to structural descriptors. If a statistically significant relationship can be derived, then it can be used to predict the property values for previously untested molecules in the *test-set*, and hence to identify those worthy of further, more detailed study. This is analogous to the use of known relevant documents to compute weights that can then be used in a relevance-feedback text search.

The development of what came to be called quantitative structure–activity relationships (QSAR) derives in large part from the pioneering work of Hansch and his collaborators.^[31,32] Hansch analysis, as the approach has come to be called, involves the use of multivariate statistical methods, such as multiple regression or partial least-squares, to correlate molecular physicochemical properties (such as the octanol/water partition coefficient or the molar refractivity that are relatively easy to compute or measure) with quantitative biological data (that are much more difficult to measure). The approach is still widely used but does have two principal limitations: it can only be applied to small sets of structurally similar molecules, typically groups that have a common central ring system and that differ just by the nature of the substituents on this central scaffold; and it is based on the correlation of physicochemical properties computed from the structure, rather than the structure itself (which can be used to compute a very wide range of types of descriptor^[33]). The latter limitation is addressed in the widely used CoMFA (for Comparative Molecular Field Analysis) approach to QSAR, where 3D variables describing the shape and the electrostatic charge of molecules are correlated with biological activity. CoMFA (and related approaches) is now the standard method for the analysis of small datasets but is still restricted to structurally related sets of molecules.^[34] With developments in high-throughput biological testing, there are now large amounts of biological data for massive, structurally diverse sets of molecules, and this data explosion is currently driving the application of machine-learning techniques (such as support vector machines, neural networks, and naive Bayesian classifiers) to chemoinformatics datasets.^[35]

Molecular Diversity Analysis

The virtual screening methods described thus far can be used if some molecules have already been tested, e.g., a

similarity search if just one active is available or a docking search if the 3D structure of the biological receptor is known. If no such information is available then molecular diversity analysis is used to select molecules for testing. The Similar Property Principle means that molecules with similar structures are expected to have similar biological activities, and hence a virtual screening model is likely to have significant predictive power only if the molecules selected for inclusion in the training set are as structurally disparate as possible. The selection of such structurally disparate sets of molecules for biological testing is effected using the techniques of molecular diversity analysis.^[36,37]

There are many ways in which a diverse set of molecules can be identified: we will illustrate the approach by cluster-based selection, which is perhaps the best established of the methods.^[38] In the present context, cluster analysis involves partitioning a database into groups (or clusters) so that the molecules within each of the clusters are strongly similar to each other but dissimilar to the molecules in the other clusters. The similarities are normally computed using 2D fingerprints (as described for 2D similarity searching) and a clustering method then applied to the sets of intermolecular structural similarity values to derive the clusters. There are many different clustering methods that can be used, with the Jarvis-Patrick and Ward methods being the most common for chemical applications. Once the database has been clustered, one molecule (normally that closest to the centre) is drawn from each cluster in turn, with the expectation that the resulting set of selected molecules will have only a limited degree of similarity. If one of the molecules that has been selected proves to be biologically active when tested, then the other molecules in its parent cluster are also candidates for testing.

ADMET Prediction

Thus far, we have focused on the use of structural information in drug discovery. However, the fact that a molecule contains the correct substructural features is not sufficient for it to be a useful drug when administered to a patient. In particular, it is vital that it has an appropriate profile of pharmacokinetic properties and that it is not toxic: for example, molecules that are rapidly metabolized in the body will be unable to exhibit the desired therapeutic activity. Historically, ADMET (standing for absorption, distribution, metabolism, excretion, and toxicity) testing was carried out once a potential drug molecule had been identified. However, it became clear that this meant that a lot of time was spent optimizing the structures of molecules that subsequently proved to be unsuitable and ADMET testing is increasingly being carried out in parallel with chemical and biological screening. In addition, in just the same way as QSAR is used to direct a research program by predicting the biological

activity of molecules that are being considered for synthesis (or acquisition) and testing, so there is much current interest in the development of ADMET methods that could predict the pharmacokinetic and toxicity behavior of molecules.

A very simple approach involves analyzing simple physical properties of successful drugs to enable an assessment to be made of the *drug-likeness* of a molecule. There is now considerable evidence that properties such as the molecular weight, the octanol/water partition coefficient, the numbers of heteroatoms, and the degree of conformational flexibility provide an effective basis for screening out large numbers of molecules that cannot possibly be effective drugs.^[39] More sophisticated approaches have adopted the statistical techniques that are used in QSAR to obtain correlations between substructural descriptors or physicochemical properties and important characteristics such as intestinal permeability and absorption, oral bioavailability, aqueous solubility, interactions with cytochrome P450s, and toxic side-effects.^[40,41]

CONCLUSIONS

The discovery of novel drugs is costly, time consuming, and scientifically demanding. The productivity of drug research is maximized if attention can be focused on just those few molecules that have a high a priori probability of success, and chemoinformatics provides a range of tools to support this aim. The brief introduction here has focused on the methods that are available for searching and for processing databases of 2D and 3D chemical structures, summarizing methods for structure, substructure and similarity searching, docking, quantitative structure–activity relationships, molecular diversity analysis, and the prediction of the pharmacokinetic and toxicity characteristics of molecules.

Children and Information Technology

June Abbas

School of Library and Information Studies, University of Oklahoma, Norman, Oklahoma, U.S.A.

Abstract

This entry presents research on the complex topic of children and information technology. Covered are children aged 0–18. Information technology has changed significantly over the last few years as has the research covered by Library and Information Science. This entry includes a brief overview of research between the years 1995 and 2009 and more in-depth coverage of the years 2010–2014. Children have increased using information technologies in every aspect of their lives to play, learn, communicate, and participate in online ecologies. A multidisciplinary perspective is taken to show that children are engaged participants, connected continuously using many technologies, including mobile devices such as smartphones and tablets, and creative content developers, but who still are plagued with poor understanding of how to effectively use retrieval systems. The technological, psychosocial, ethical, security, and legal issues children encounter while online are also presented.

INTRODUCTION

Children and information technology is a very broad topic, thereby requiring broad coverage. For the ease of the reader, the term “children” will be used to indicate both children [ages 0–11] and young adults [ages 12–17]. This entry does not include discussion on young adults between the ages of 18 and 26. The term “information technology” is defined broadly as “any electronic format designed to help people access information.”^[1] This definition allows us to include any textual, audio, video, image, or virtual media, including the Internet and World Wide Web, as well as mobile technologies such as smartphones and tablets. The popular perception is that children are “digital natives” who are adept at using information and communication technologies.^[2] This population of children represents the first group who have grown up with technologies such as computers, mobile devices, and social media interwoven into many aspects of their lives. The research, as will be outlined within this entry, is beginning to paint a picture of children as engaged, connected, creative users, not just consumers of information technologies, but who are still plagued with issues of information illiteracy and poor understanding of how to use retrieval systems effectively.

Along with technology use are the psychosocial, ethical, security, and legal issues that children face daily as they interact in the new information ecologies or “networked publics”^[3] of the Web, and particularly, social media. As we learn more about how children are using, and are users of, information technology, it is important to remember that children will still go through the same experimental, explorative process of play, communication, and emotional and psychosocial development as

children always have, and to them information technology is a necessity in many of their social worlds.

This entry does not seek to provide a comprehensive review of all of the literature, but rather will synthesize our understandings of children’s use of information technology and to present important research areas being explored in Library and Information Science. As some of the research is multidisciplinary, guided by theories and studies within the fields of Education and Communication, this entry will include studies from those fields as relevant to understanding the complex relationship between children and information technology and to explore sociocultural issues not fully addressed in library and information science literature. Furthermore, as previous editions have provided coverage of earlier research, this entry will include only a brief summary of research conducted prior to 2010. For earlier research, refer to previous editions of this entry.^[4–6]

OVERVIEW

Children globally have unprecedented levels of access to information technology, whether through the use of computers located in their homes, schools, libraries, or other locations, or through their cell and smartphones or other mobile devices. For example, China has invested significant effort to add information and communication technologies (ICTs) to schools. In 2007, 270,000 elementary and secondary schools in central and western regions added facilities with ICTs, with the majority of these facilities connected to the Internet for the first time.^[7] Schools in remote rural areas, however, in 2008 remained largely unconnected.^[8] The International Telecommunication

Union has estimated the worldwide population of digital natives as 363 million or 5.2% of the world's population of 7 billion in 2012. They define digital native as the population of networked youth, aged 15–24, with 5 or more years of online experience. This estimate equates to 30% of the world's youth population as digital natives. Digital natives, however, still represent a minority among the world's youth due to low Internet usage rates in developing countries. The total population of digital natives varies between countries, from 0.1% in Timor-Leste to a high of 14% in Iceland; median population of digital natives in Belarus and Syria with 5.5 and 5.4, respectively. Notably, the populations with the highest proportions of digital natives are all high-income or upper-middle-income countries with very high overall levels of Internet penetration, including Iceland, New Zealand, Republic of Korea, and the United States (19).^[9]

Other studies focused on the U.S. children reveal that information technology use begins at a very early age. A 2013 study conducted by the Common Sense Media group found that U.S. children aged 8 and under spend an average of 1 hour and 55 minutes a day with screen media, an increase of 21 minutes spent in 2011. Screen time measured included watching TV, playing video games, using a computer, and using mobile devices such as smartphones and tablets (15).^[10] Further telling is that in 2011 only 8% of children aged 8 and under had access to and used tablets, while in 2013 this figure increased to 40%, with many of the children having access to their own tablets, not having to share it with other members of the family. Smartphone ownership within the family has also increased from 41% in 2011 to 63% in 2013. Use of mobile devices has also increased for this age group and begins at a young age, with 38% of children of age 2 and under using a mobile device for any media activity, compared with 10% in 2011. Among 2- to 4-year-olds, the rate increased from 39% in 2011 to 80% in 2013; and among 5–8-year-olds, from 52% to 83% in the past 2 years (20).^[10] Older children (ages 12–17) have been the focus of multiple large-scale studies. For example, a 2012 joint Berkman Center for Internet & Society at Harvard (Berkman) and the Pew Research Center (Pew) study found that 78% of U.S. teens (ages 12–17) own a cell phone, with half of those phones being smartphones. This figure is an increase over 2011, in which only 23% owned smartphones. One in four teens or 23% own a tablet; three in four or 74% say they primarily access the Internet on cell phones, tablets, and other mobile devices. Thirty-four percent of teen girls aged 14–17 report that they mostly go online using their cell phone, compared to 24% of boys in the same age range. Fifty-five percent of teen girls who own smartphones report they access the Internet mostly from their phone (2).^[11] It is also important to note that a digital access divide still exists among teens from lower-income households. Teens in lower-income and lower-education households are “still somewhat less likely to

use the Internet in any capacity”; however, the income and education level of parents does not affect the likelihood that teens in these families own cell or smartphones (7).^[11] Increased access to information technologies provides children, especially older youth, with opportunities to learn, play, create, socialize, and participate in civic life at unprecedented levels than earlier populations of youth.

AREAS OF RESEARCH

Research Prior to 1995 (years of each section based on years that correspond to earlier editions of this entry).

There is a rich history of research on children's use of information technology, with the majority of the research focusing on older children (middle and high school students of ages 11–17), and much of the research employing small, nonrepresentative samples. Research prior to 1995 (when more widespread use of the Internet and World Wide Web began) focused on children's use of electronic resources, such as online public access catalogs (OPACs), databases, and CD-ROM software in libraries and school media centers. This body of research on children's use of electronic resources “reflected the pragmatic concerns of librarians and educators who saw a need to train students in the effective use of these new information resources” (2).^[12] Much of the research during the 1980s and prior to the Internet use provided descriptive data on which schools provided access to electronic resources, and the effect (whether positive or negative) using these new electronic sources had on children's information retrieval abilities. It examined the role that system design, search skills such as formulating Boolean searches, and the use of synonyms, truncation, and controlled vocabularies had on children's abilities to find information in electronic resources. Research did not focus on children's information seeking behaviors and the cognitive, physical, emotional, etc. factors that might affect retrieval.^[12] The reader is referred to Cool^[12] and to an earlier edition of this entry^[4] for further coverage of the research conducted in the 1980s and prior to 1995.

Research 1995 through 2004

Research conducted between the years 1995 and 2004 continued to explore children's use of electronic media, but it also began to examine 1) how children were using the new technologies of the Internet and World Wide Web, search engines, and digital libraries (for a comprehensive look at children and the Web during this time span, see Large^[13]); 2) other information technology devices such as electronic books (e-books) and PDAs; 3) collaboration between children and technology designers; 4) use of computers in libraries and schools; 5) the impact Internet access and use had on children's use of the public library; and 6) use of new technologies to reenergize old

practices (blogs, e-books, literature circles). Also investigated were older children's selection criteria of Web pages and the factors considered when librarians design Web pages for use by children. Refer to the 2003 and 2005 editions of this topic^[4,5] for more in-depth descriptions of the research conducted during 1995–2004.

It is also important to note that beginning in 2001, several large-scale national surveys within the United States as well as in Canada were conducted to learn more about children's online activities while they use the Internet. The Pew Research Institute's American Life Project^[14] conducted numerous surveys using both nationally sampled, random digit dialing telephone surveys as well as focus groups with children and their parents. Other groups, such as Environics Research Group, the U.S. Department of Education, Grunwald Associates with cooperation of the Public Broadcasting Service, also conducted large studies on youth's online activities in the United States and Canada. The results of these surveys served as our main source of nationally representative, generalizable findings on what activities children engaged in while online, locations of access,^[15,16] attitudes of parents and children,^[17] and youth's educational and recreational uses for information technologies (included teachers' perspectives as well).^[18] These earlier studies helped us develop a more complete view of what children were doing online, the activities they engaged in, and their attitudes, opinions, and purposes for using the Internet. Findings indicated that 1) children viewed themselves as tech-savvy, especially more than their parents and/or teachers; 2) the Internet played a pivotal role in children's lives and they both rely on it and value its use; and 3) children used the Internet for communication with friends, to surf for fun, and for recreational and educational purposes. These studies did not, however, reveal any findings about children's information seeking processes, problems encountered while searching and using search engines, nor the effect cognitive, developmental, physical, or emotional variables can have on children's search success.

Research 2005 through 2009

Research conducted in 2005 through 2009 continued with and expanded upon the research emphases of prior years (information seeking processes and factors that affect retrieval of digital resources, the role that children can play in collaborative design of systems for children, i.e., digital libraries, search engines, Web pages, and children's online activities). Information seeking success can be influenced by many cognitive, developmental, and system factors. Previous research findings indicate that children in all age groups encounter a range of difficulties while searching for information due to 1) a lack of understanding about how the system works; 2) limited search and semantic skills; 3) the system's use of an inappropriate controlled vocabulary to describe the resources;

4) resources were not current, not age-appropriate or contained incomplete or low-quality information; and 5) systems were not designed for children and included features that distracted children and/or made navigation confusing and inefficient. During 2005 through 2009, research continued to help us understand children's search processes, the factors that impact children's success while seeking information, and their seeking within specific contexts (OPACs, databases, the Internet using search engines, and digital libraries). Beginning in 2005, two new areas of research appeared in the literature on children's information seeking. These areas included the effect of affective variables such as emotion on information seeking outcomes and the multicultural use of information technologies, mostly in the context of digital libraries. While affective variables are not new to studies conducted in the fields of psychology, computer science, education, or cognitive science, affective variables have not been emphasized as a research area in information science until recent years. Bilal^[19] explains that children "need to possess not only adequate information-seeking skills but also intelligent affective strategies that will help them cope with its [information technology's] complexity" (198).

Also of importance, during the years of 2005–2009, we saw a radical shift in how children interact with information technology. Instead of just being passive users of information technologies such as library OPACs and the Internet to locate information, children, especially older children, became very active content creators, designers, teachers, and participants in social networking, gaming, and virtual environments. This "shift" opened up new areas of research, as well as presented many pragmatic, ethical, and safety-related issues for children, their parents, and practitioners and libraries. While our understanding of children's use of the Internet is informed by the areas of research outlined earlier (use of electronic and multimedia resources, their information-seeking activities, the problems they encounter when using systems, and the cognitive, affective, physical, and developmental factors that can impact their system use and retrieval activities), examining children's use of the Internet is a very complex issue that requires us to not just look at their use through a traditional information-seeking and system use lens but rather, we need to look broader at the activities and environments they engage within, the social issues that are becoming more prevalent with universal Internet access such as cyberbullying, privacy, and safety. New areas of exploration during this time period were related to 1) the use of social networking sites, such as MySpace and Facebook;^[20] 2) content creation on blogs and social sharing sites such as YouTube;^[21] 3) social issues of cyberbullying, identity, privacy, and safety;^[22–24] and 4) information technologies used for communicative purposes, including cell phones, email, and texting.^[20,25] Refer to the 2010 edition of this topic for more on the research conducted during 2005 through 2009.^[6]

Research 2010 through 2014

The research emphases that had begun in earlier years became even more important in 2010 through 2014 as more researchers focused on the “digital native” or “digital youth” and understanding more about their information behaviors, information literacy, online participatory activities, and the impact the information technologies had on their intellectual and psychosocial development. Much of the research during this time period is on older children, or teens, with scant research focused on younger children. While traditional research areas of information behavior and information retrieval continue to help build understanding of the digital youth, much of the research during this time period focused on youth’s use of and participation in online ecologies, such as social networking and collaborative sites. Research of youth within this context has explored their frequency and motivation of use, psychosocial issues such as identity development, privacy and safety issues, and the potential benefits and drawbacks of participating in online environments. This section will outline the research areas prevalent during this time period with examples of research that contribute to our understanding of children and information technology.

Information behavior

Research on the information behaviors (IBs) of children can help us better understand today’s digital youth. Wilson defines IB as “the totality of human behavior in relation to sources and channels of information, including both active and passive information seeking, and information use.”^[26] Information behavior can be purposive, having a specific goal in mind, and may be engaged in as part of a person’s everyday information activities. Several models have been proposed throughout the years to portray the iterative, interactive, dynamic processes humans engage in when browsing or seeking information to meet an information need. (Refer to Fisher et al.^[27] for discussion on information behavior models.) The research conducted between 2010 and 2014 included various contexts and frameworks for understanding information behavior of youth, including for example, studies based on the everyday life information seeking (ELIS) framework, the creating behavior of youth as an additional aspect of IB,^[28,29] health information seeking,^[30–35] information behaviors of specific populations^[36,37] who examined the understudied population of Latino youth in poor California communities, and studies concerned with information retrieval factors.

Everyday life information seeking

The everyday life information seeking (ELIS) framework was proposed by Savolainen and has been adapted by other researchers. The ELIS framework describes an individual’s daily life information activities and the role

information plays in decision making. Furthermore, it proposes that the individual habits we form when monitoring daily events and seeking information, as well as the sources and channels we use to find information, are based on values, attitudes, and interests learned in sociocultural contexts.^[38] A chapter by Abbas and Agosto,^[39] in Behesti and Large’s recent book on the information behavior of the digital generation,^[40] outlines research in youth’s ELIS and describes how ELIS is useful in understanding digital youth. Synthesis of the research to date on youth’s ELIS found:

- Youth search for information for various purposes (problem solving, coping, entertainment, self-development).
- Youth prefer to use informal human channels first, such as family and friends and use various information technologies to communicate with friends and family.^[41,42]
- Youth use the Internet to find information related to various everyday information needs, for entertainment, and to participate in social networks.^[39]

What ELIS research has not uncovered is whether or not youth are using information technologies such as cell and smartphones and social network sites to find information. Many of the ELIS studies outlined in this entry took place prior to large-scale adoption of information technologies by youth but the research has illustrated how this framework can be very useful for understanding digital youth.

Creating behavior

The most prevalent models of information behavior include the recognition of an information need and the process an individual follows to satisfy that need. What is generally not explored is the complex creation process undertaken by youth when they use found information to develop new information or products. Online environments afford youth many opportunities to create information products such as YouTube videos, websites, social media posts, online photos posted on sharing tools (e.g., Flickr, Snapchat, Instagram). Youth creating behavior, then, would seem to be a necessary aspect of understanding their information behaviors; however, few studies to date have explored this component of information behavior. Harlan et al.^[29] and Koh^[28] have proposed that creating behavior be included in information behavior models. Harlan asserts that “the affordances of social media—ease of use, ubiquitous access, and communal nature—have made creating and sharing content an appealing process for teens.” (p. 569) She also links creating behavior to learning and information literacy. Her research explored how teens experience using information to learn as they engage in online communities. Koh examined older children’s information creating behaviors while participating in an online community using the programming tool Scratch. Her findings indicate that creating behavior

includes 1) the development of content, 2) organization, and 3) presentation of information. Furthermore, the findings illustrate the complex processes youth engage in when creating content in online, collaborative environments, including 1) visualizing (using visual tools and multimedia to communicate their ideas); 2) remixing (building on or adding to the original information or projects of others and then sharing the product with others); and 3) tinkering (iterative design process youth engage in while creating). Youth also felt a sense of empowerment as they contributed to the Scratch community and took on new, more responsible roles. Koh's study also shows how youth seek and evaluate information from multiple sources to determine their accuracy and how they demonstrated an understanding of the relationships connecting the various sources they used.

Health information seeking

Health information seeking by youth has increased in recent years. Fox and Jones in 2009^[43] found that 28% of older youth (12–17) have used the Internet to look for health-related information. In 2010, Purcell and Lenhart^[44] reported that of the 93% of the U.S. youth (aged 12–17) who went online, 31% had searched for health information. Furthermore, a multidisciplinary literature review between the years 2000 and 2012^[31] examined 82 articles on teen's health information seeking and found that 57% of teen health information behavior studies were focused on specific topics such as sexual health, mental health, nutrition and eating issues, and those related to alcohol, drugs, and tobacco; 43% covered more general health topics. The majority of the studies included online resources as the context of the study, with 47% focused only on online resources and 36.5% including both online and other types of resources. The review also found that the number of studies focused on teen health information seeking increased beginning in 2011. Health information behavior studies have examined many aspects of youth information behavior including 1) the information coping strategies and online activities of young people,^[30,34,35] 2) searching for nutrition-related information,^[45] 3) using text messaging and other information technologies to assess adolescents' health information needs,^[32,46] 4) the issue of trust as a factor in user-centered design of systems promoting sexual health in African-American youth,^[33] 5) the use of social media to find health information,^[47,48] and ELIS as a way to understand the "coming-out-process" of gay youth.^[49]

Information retrieval

Information retrieval studies are concerned with the seeking or retrieval process of information behavior. The studies include models of information seeking/seekers, search processes, barriers to retrieval, and factors to consider in retrieval system design. Research during 2010 through

2014 continued to explore children's web searching and technoliteracy;^[50–54] roles that youth of all ages display while seeking information;^[55,56] and innovative ways to increase precision and recall in systems designed for children.^[57] As noted earlier, children encounter many issues when searching for information using information technologies. Today's digital youth are no exception. Research has shown this to still be an issue in children's information seeking. For example, Spink and colleagues studied web searching of 4- and 5-year-olds and discovered that young children use search engines to both search and browse for information. Young children are also capable of complex web searches, could evaluate sources for relevance to their query, and engaged in successive, collaborative search behaviors like those of adults. Their technoliteracy was measured as competent as they proficiently used the mouse, cursor, and keyboard to effectively navigate the websites. The children did, however, exhibit issues while constructing queries related to spelling and word acquisition.^[50] Behesti, Large, and Tam's study of transaction search logs from a Canadian history web portal designed for children showed that children preferred to browse using the topic taxonomy feature, followed second by the alphabetical word search (combined 83%), rather than search using key words or the advanced search feature.^[53] Bilal and Ellis^[51] and Bilal^[52] took a different approach as they compared the performance of five search engines, two being specifically designed for children, and found that the engines designed for children did not perform as high as, based on relevance of documents retrieved, the larger engines. The child-centric engines did, however, retrieve higher precision results on partially relevant results. The results of the studies illustrate that children continue to encounter many barriers when searching for information on the Internet such as using advanced features of engines that enable them to filter results, the ability to formulate effective search strategies and to interpret and evaluate the results retrieved, and possessing adequate reading skills (189).^[52]

Teachers also provide a valuable perspective on children's information literacy and technological fluency. A survey of Advanced Placement (AP) and National Writing Project (NWP) teachers revealed that teens' research habits are changing in the digital age. The study findings indicate that 75% of AP and NWP teachers report that while the Internet and search tools have had a mostly positive effect on students' research habits, 87% said these technologies are creating an "easily distracted generation with short attention spans," and 64% say "today's digital technologies 'do more to distract students than to help them academically'" (2).^[58] Some of the positive effects include access to a "greater depth and breadth of information on topics that interest them," engaging multimedia formats, and that many become self-reliant searchers. Teachers are, however, concerned with increasing dependence on search engines, the difficulty children have on judging reliable,

quality information, increasing distractions, poor time management skills, and the general level of literacy of children (2).^[58] Furthermore, the teachers report that the Internet has changed the nature of research. To children, research means “Googling,” in which the student no longer engages in a slow, intellectual process of discovery, but rather is concerned with quickly finding just enough information to complete the assignment (3).^[58]

Teachers also noted many barriers to incorporating information technologies into their classrooms, such as policies restricting use of cell/smartphones in school, Internet filters on school computers, and provisions in a school’s acceptable use policy (5).^[58] In a related report from the Berkman Center for Internet & Society at Harvard University (Berman Center), youth report similar observations. Youth reported a wide variety of school policies related to laptop use, phones, iPads, and other mobile devices and how the policies served as barriers to access. An interesting finding was that youth mentioned being frustrated with school initiatives to provide them with new tablets for academic purposes when they would have preferred laptops instead.^[59]

While most information retrieval studies of children take place in schools, libraries, or in laboratory settings, Foss and colleagues^[55,56] studied children of ages 7, 9, 11, and 14–17 in their homes. The goal of their study was to understand how children search the Internet in their homes and to uncover potential triggers to searching, search rules, emotional and social factors encountered, and how they handle multistep, complex search tasks. Their study developed a framework of seven search roles children can be characterized by including 1) Power (awareness of sources to use and ability to use advanced search features); 2) Developing (limited knowledge of search tools, unable to plan searches or to verbalize their search process, and use a variety of search approaches); 3) Distracted (tendency to drift easily off task, and to encounter information not related to the task); 4) Nonmotivated (compliant with directions to search but generally do not choose searching or the computer as an activity); 5) Domain-specific (use search abilities to gather information on specific topics of interest); 6) Visual (a desire to retrieve information from visual sources, like pictures or videos); and 7) Rule-bound (displayed constrained searching patterns, repeating the same steps each time).^[55] Younger children (ages 7, 9, 11) displayed different roles than adolescents. For example, there was an absence of Distracted Searchers in adolescents, while an additional role emerged for adolescents, that of Social Searcher, whose main use of the computer was driven by social factors such as communicating with friends using social networking sites. The other notable difference between younger children and adolescents was that Power searchers were more advanced in their searching than younger children (178–179).^[56] These studies illustrate that children do not all search the same, in fact they take on a variety of different roles when

searching. Gossen and Nurnberger^[60] note that one of the current problems in IR research for children is that researchers view children as a consistent user group. Furthermore, researchers do not consider that children of different age groups may require different solutions that influence the design of information systems. The studies outlined here, as well as earlier studies by Bilal and other researchers,^[5,6] illustrate how children’s abilities differ from adult searchers, their ideas of research and how to find useful information are changing, and that age and cognitive abilities are factors that still require further exploration.

Internet Use: Social Networking

During 2010 through 2014 the use of the Internet increased with an estimated 95% of teens in 2012 reporting they go online. Eight in ten online teens have used some form of social media (19).^[61] Online environments have changed the way that people seek information, interact with others, contribute to participatory cultures, create, learn, and play. LIS research on the Internet during this time period continued to focus on the pragmatic, ethical, legal, and literacy issues related to use of the Internet and social networking sites. Research of youth in social networking sites has explored their frequency and motivation of use, information technologies used to go online, psychosocial issues such as identity development and privacy and safety issues, and the potential benefits and drawbacks of participating in online environments. Anttiroiko and Savolainen^[62] defined Social Network Sites (SNS) as “profile-based hosted services that allow people to create and maintain networks of friends and contacts based on general social interests” (p. 89). Examples of the most popular SNS currently are Facebook and Twitter, though use of SNS continues to change as new different, subject-specific, or media-specific sites appear. For example, Instagram and Snapchat are becoming favorite sites among older children. These new SNS allow teens to post images and/or short videos that can be instantly shared with friends, without requiring the content development and upkeep of a Facebook profile page. The sites allow teens to communicate quickly and easily with their friends, without the drama or time investment of Facebook.

Compared with adults, U.S. teens are heavy users of SNS. In 2012, 77% of online teens reported they have a Facebook account (81% reported using social media), and 24% of them used Twitter, while 67% of adults used social media and 16% used Twitter.^[61] Research related to SNS use by children has also continued to increase. A multidisciplinary literature review conducted by Agosto and Abbas in 2012, including studies focusing on youth between the ages of 12 and 18, showed that 38 studies were published between the years 2006 and 2011. Their study concluded:

The burgeoning body of literature paints a multifaceted picture of youth people's SNS practices, and the major issues that surround their participation in social networking communities. For the most part, the kinds of activities taking place in SNS are the same kinds of activities that took place offline among previous generations of young people. The difference is not so much the kinds of activities that are occurring online, but the *amount, frequency, and semipublic nature* of these activities (pp. 123–124).^[63]

This conclusion is supported by other researchers such as Boyd,^[64,65] and Livingstone and Brake.^[66] Agosto and Abbas outline major themes in the literature including:

- Motivation (social interaction/communication,^[41,42,64,65,67–75] relationship building and maintenance,^[41,42,68–71,76–79] emotional support,^[68–70,80] convenience^[41,42,71,81]).
- Benefits (identity exploration and formation,^[64,65,68–70,78,80,82–87] technological literacy,^[67,70,77,80,86,88,89] educational support/formal learning,^[73,86,85,90] positive self-esteem^[41,76,91]).
- Harms (privacy risks,^[67,92–95] security risks^[41,67,92,94–101]).

These themes have been reflected by the large-scale studies conducted on this topic between 2010 and 2014. More recent studies are outlined briefly as follows.

Bullying in a Networked Era:^[102] As part of the Kinder and Braver World Project at the Berkman Center for Internet & Society at Harvard University (Berkman Center), this report provides a multidisciplinary literature review of academic research on the topic of bullying. The review focuses on research published between 2008 and 2012 but includes some important earlier studies as well. The study captures both offline and online bullying and is guided by two questions, “What is bullying?” and “What can be done about bullying?” A companion to this report is an overview of state antibullying legislation and other related laws in the United States.^[103] This report provides an overview of existing and pending antibullying state legislation, as well as specifics of how the laws define and address bullying, cyberbullying in multiple contexts, and procedures for reporting and prosecuting offenses.

Teens and Technology 2013:^[111] This report, a collaborative effort by the Pew Research Center's Internet and American Life Project and the Berkman Center, describes cell and smartphone adoption among teens and how using cell or smartphones has afforded them 24/7 mobile access to the Internet. See Overview section for key findings.

Social Media, Social Life: How Teens View their Digital Lives:^[104] This Common Sense Media research study gives another glimpse into teens and their use of social media. Their study complements other studies

conducted by Pew and the Berkman Center. Key findings include:

- Nine out of 10 or 90% of 13–17-year-olds have used some form of social media.
- Seventy-five percent have a profile on a social media site; 22% have a Twitter account.
- For the vast majority of teens, social media and other forms of digital communication are a daily part of life. Sixty-eight percent text every day; 51% visit social media sites daily; 34% visit their social media site several times a day; 11% receive tweets at least once a day.
- One in four (23%) are “heavy” social media users and use at least two different types of social media every day (9).
- Most teens prefer face-to-face communication. About 49% prefer in person communication with friends. Texting is their next favorite (33%), followed by social media (7%), talking on the phone (4%), and tweeting (1%). They prefer in person communication for various reasons, mostly because it is fun (38%) and they can understand what people mean better (29%) (11).
- Some teens wish they could disconnect more often and that others would too. Forty-one percent said they were “addicted” to their phones; 43% strongly or somewhat agree and wish they could unplug sometimes. The teens who reported they are most interested in unplugging are the ones who either are not using social networking or who have had a bad experience online (2).

Teens, Social Media, and Privacy:^[61] This report, a collaborative effort by the Pew Research Center's Internet and American Life Project and the Berkman Center, provides up-to-date research on teen's (ages 12–17) use of social media, their sharing and privacy practices, and impressions of online privacy. Some key findings include:

- Teens are sharing more information about themselves on social media than they did in the past; 91% post photos of themselves, 71% post their school name, 71% post their city or town, 53% post their email address, and 20% post their cell phone number. These figures differ across age, with older teens (14–17) sharing more content than younger teens.
- The typical teen Facebook user has 300 friends, while the typical teen Twitter user has 79 followers. Older teens tend to be friends with a variety of people than younger teens, with most of their friends being people they know.
- Teens are losing interest in Facebook and reported a dislike of the adult presence, people sharing excessively, and the stressful drama in many of the posts as

reasons. They continue using Facebook because it is an essential part of teen socializing.

- 60% of teens keep their profiles private and say they can confidently manage their privacy online.
- Teens use multiple measures to maintain their reputations online and to manage their networks, including for example, deleting people from their friends/followers list, pruning their profile content, posting false information such as fake name, age, or location.
- Teens did not report a high level of concern about third-party access to their data, only 9% reported they were “very concerned.”
- Teens reported more positive experiences than negative experiences (2–7).

Where Teens Seek Online Privacy Advice:^[105] This report, a collaborative effort by the Pew Research Center’s Internet and American Life Project and the Berkman Center, sought to determine the resources teens used to learn about protecting their online privacy. Some key findings include:

- Teens (ages 12–17) in the United States care about their online privacy and take steps to manage access to their online social media spaces.
- Many teens report relying on themselves for learning about online privacy measures; however, the majority of teens (70%) found themselves asking for outside advice at one point
 - 42% asked a friend or peer for advice
 - 41% asked a parent
 - 37% asked a sibling or cousin
 - 13% used a website for advice
 - 9% asked a teacher
 - 3% have gone to some other source
- Younger teens (12–13) are more likely to seek out advice than older teens.
- Girls are also more likely to seek out advice than boys.
- White teens from high-income and high-education households are more likely to turn to parents for advice.
- Teens who have sought advice take similar measures to protect their online presence as do those who have not sought advice.

It is evident from the research that social networking sites figure prominently and are an essential part of children’s lives. The data show that almost all teens have used social media at some point, many use more than one site, and may visit the site more than once a day. Teens are, however, becoming less enthusiastic about using some social media, such as Facebook, and wish they could disconnect at times and that others would do so also. Children feel that they do a good job of managing their online profiles and employ various measures to keep their information private, though at the same time, they are not worried about third-party access to their personal data.

Digital Media, New Literacies, Digital Youth

A related research area which serves to help us better understand children and information technology is that of digital media use and new literacies from the fields of education and communication. While a bit out of scope for this entry, what we are learning from studies in this area is informing research and practice, specifically in public and school libraries. To study the “digital native” or “digital youth,” Ito and colleagues undertook a ground breaking study to explore the social and cultural influences of new media practices on today’s youth, and to determine how digital media are changing the way young people learn, play, socialize, and participate in civic life. Their 3-year multiproject study funded by the MacArthur Foundation included a comprehensive ethnographic study of 700 youth. The researchers developed a framework of “genres of participation” that helped to describe different levels of commitment of youth engagement with new media such as social networking sites, YouTube, or chatrooms.^[72,106] According to Ito and colleagues, “Instead of looking to rigid categories that are defined by formal properties, genres of participation are a way of identifying, in an interpretive way, a set of social, cultural, and technological characteristics that participants recognize as defining a set of practices” (16).^[72] Ito and colleagues’ genres of participation include:

- *Friendship-driven* genres of participation, the dominant and mainstream practices of youth as they go about their day-to-day negotiations with friends and peers in various contexts, such as school, religious groups, school sports, and other local activity groups. Facebook is an example of an online context for friendship-driven genres of participation.
- *Interest-driven* genres of participation put specialized activities, interests, or niche and marginalized identities first. Interest-driven practices of youth are described by young people as “the domain of the geeks, freaks, musicians, artists, and dorks, who are identified as smart, different, or creative, and who generally exist at the margins of teen social worlds” (13).^[72] Interest-driven genres of participation are driven by a young person’s interests in hobbies, finding information on specific topics, and in their desire to be seen as an “expert” in their particular interest. Relationships are formed on this premise, rather than for social or interaction interests as seen in the friendship-driven genre.

Ito and colleagues also determined that young people engage with media at different levels of commitment: “1) they ‘hang out’ with friends in social spaces such as Facebook and MySpace; 2) they ‘mess around’ or tinker with digital media, making simple videos, playing online games, or posting pictures in Flickr; and 3) they ‘geek out’ in online groups that facilitate exploration of their core interests” (9).^[3,72]

This typology of engagement by digital youth is called HOMAGO and is the basis for the connected learning philosophy [website], and the pedagogical framework for emerging interactive learning spaces in libraries and museums called Learning Labs and Makerspaces.

Dresang's Radical Change Theory may provide the bridge that is needed to explore the issues associated with digital youth's media use and ELIS. Dresang and Koh^[107] suggest using Radical Change Theory as a framework for understanding more about how digital youth think and seek information, perceive themselves and others, and access information and seek community. They explain that Radical Change theory is "based on the digital age principles of interactivity, connectivity, and access. This theory provides a promising theoretical framework for explaining contemporary changes in information behavior and resources as well as for serving as a guide for investigative studies and professional practice." (27) The typology^[108] includes three facets:

1. *Interactivity* refers to the dynamic, nonlinear, and nonsequential learning and information behavior in the digital age.
2. *Connectivity* is the sense of community and development of online social worlds that have emerged from young people's changing perspectives and expanded associations.
3. *Access* is described as breaking down the longstanding information and access barriers and giving young people access to a wider diversity of formerly largely inaccessible opinions.

Building on Dresang's earlier typology and incorporating findings from new media studies,^[72,106,107,109–111] Dresang and Koh extended the theory to identify three types of information behavior of digital age youth. The three types include:

1. Type One: Changing forms of seeking information and learning (or how youth seek information and learn)
 - a. obtaining information from a variety of sources
 - b. multitasking
 - c. preference for graphic and visual information
 - d. seeking information nonlinearly and nonsequentially
 - e. developing self-defined and controlled paths
2. Type Two: Changing perspectives (or how youth perceive themselves and others)
 - a. expressing opinions for themselves
 - b. portraying flexible and multiple identities
 - c. encountering information from various perspectives
3. Type Three: Changing boundaries (or how they access information and seek community)
 - a. obtaining instant access to a wide array of information

- b. seeking, sharing, and creating information collaboratively
- c. forming new types of social networks
- d. participating in community engagement (29).^[107]

An outcome of the digital media, new literacies, and connected learning initiatives that is directly related to LIS and to libraries specifically is the integration of technologies into interactive learning spaces, such as Learning Labs or Makerspaces, to facilitate STEM learning. Little research has been done on the efficacy and usefulness of these spaces and while the literature itself is proliferating almost as quickly as these new spaces themselves, it focuses mainly on: 1) history and models of Makerspaces/Learning Labs;^[112,113] 2) case studies or informal reports of how specific libraries or museums developed their Makerspace or Learning Lab;^[114–116] 3) advice and resources for how to start a Makerspace or Learning Lab;^[117,118] and 4) models and technology suggested for use and sample projects.^[119] The limited research literature relates to surveying libraries in the United States and seven other countries about the presence of Makerspaces in their organization or their plans to develop one in the future; issues related to funding, programming, and the top technologies used by library Makerspaces^[120] and a study by Koh and Abbas about the competencies needed by library and information professionals who work in Learning Labs or Makerspaces in U.S. libraries or museums.^[121]

CONCLUSIONS

The research focused on children and information technology shows a picture of children as digital youth who are engaged, connected, creative users, not just consumers of information technologies, but who still encounter many issues when searching for information using information technologies. Information behavior and retrieval studies provide us with a better understanding of how children use information technology to search for information they need for activities and decision making within their everyday lives, to create within collaborative environments, and the roles children display while searching online. Research has also found that social networking sites have become even more essential in the daily, digital lives of children, thereby requiring more research into the socio-cultural, psychosocial, ethical, legal, and pragmatic issues faced by youth as they use these information and communication technologies to engage with others. As we learn more about how children interact with information technology, and within digital ecologies, it is important to remember that children are still children who will still go through the same experimental, explorative process of play, communication, and emotional and psychosocial

development as children always have, and to them information technology is a necessity in many of their social worlds.

ACKNOWLEDGMENTS

My sincere thanks to my research assistant, Anna-Rose Cozad, for her invaluable assistance in searching, sifting, and making sense of the morass of literature on children and information technology. I would also like to thank my long-time collaborator and friend, Dr. Denise Agosto, for always championing the view that children and information technology must be studied as a unique subgroup but also approached from a holistic perspective.

Children's Literature

Judith V. Lechner

Department of Educational Foundations, Leadership, and Technology, Auburn University,
Auburn, Alabama, U.S.A.

Abstract

“Children’s Literature” describes literary works written for children and young adults. The entry uses a genre approach to organize the literature and focuses on historical and contemporary English language and to a lesser degree international children’s literature that has been translated into English.

INTRODUCTION

The adults concerned about the books children read—parents, educators, authors, editors, critics, though not the children—define “literature” using demarcations based on quality, genre, and even format. The poet Walter de la Mare’s comment that “only the rarest kind of best in anything can be good enough for the young” (cited in Silvey, p. 121),^[1] exemplifies the emphasis on literary quality in books for children, as do most literary awards such as the Newbery and Caldecott Medals. Instructions for the awards committees state that popularity is not a consideration. In terms of genre, “literature” is often restricted to imaginative writing. Although occasionally the Newbery Medal has been awarded for informational books and biographies, not until 1990 and 2001 did the National Council of Teachers of English and the American Library Association (ALA), respectively, establish awards for informational books and biographies for children. Concepts of formats that can be considered literature have also changed over time. Two graphic novels, a format that was formerly labeled “subliterature,” were recognized for the first time in 2007 by two ALA awards.

Childhood too is a relative concept. The age of responsibility, when childhood is considered to be at an end, has risen since the beginnings of the industrial revolution, while the age at which children are considered capable of comprehending complex issues, from sexuality to social problems, has fluctuated across both time and place. The trend since the 1960s has been to introduce complex issues to children at younger ages than in the nineteenth and early twentieth centuries, but serious social issues are more likely to be introduced in European than American children’s books for elementary school age children.^[2]

This entry will use Rebecca Lukens’s definition of children’s literature in *A Critical Handbook of Children’s Literature*: “...the body of writing that exists because of inherent imaginative and artistic qualities” (p. 3).^[3] Lukens emphasizes the importance of pleasure the author aspires to evoke in the implied reader, the child; the

understanding the work is likely to engender through the “exploration of the human condition”; and the form literature provides for the reader to make meaning of the fragmented experiences of life (pp. 4–6). Children’s literature will refer to literature written for an audience from the youngest child to age 14, the limitation set for the Newbery Medal, but each section of the entry will also discuss literature written for young adults, which refers to literature that considers the perspectives and interests of young people between ages 11 and 18. After a brief history of children’s literature, the entry will discuss various genres of children’s and young adult literature; international and multicultural children’s literature; and nonbook media, and will list literary awards and some of the major organizations devoted to children’s literature.

HISTORY OF CHILDREN'S LITERATURE

The history of children’s literature in the sense the term is used today, is no more than 250 years old. Social, economic, and technological factors contributed to its development in the industrializing England of the eighteenth century. Similar developments took place elsewhere in Europe and North America in the nineteenth century and in East Asia in the late nineteenth, early twentieth centuries. Children’s literature in Latin America, Africa, and much of Asia has been developing since the middle of the twentieth century. The costs of paper, printing, and distribution, as well as standard of living affect the extent to which a country or region can afford to create books for children.

For most of human history, children and adults shared the orally transmitted stories passed on within communities for the purpose of acculturating, instructing, and entertaining them in both secular and sacred matters. Some recorded fables and books of prayer, however, did become available to children and were used for their education. Manuscripts of Aesop’s fables, for instance, were used throughout Western Europe in the Middle Ages to teach

Greek and Latin, rhetoric and grammar, as well as ethical behavior to a small minority of children.^[4,5] The majority of children, however, continued to be educated through sacred and secular oral narratives; drama; poetry and nursery rhymes; and visual representations.

The democratization of literacy and the slow evolution of material published expressly for children began with the development of the printing press by Gutenberg in the mid-1400s. One of the first English printed books, published in 1484, William Caxton's *Aesop's Fables*, however, was not meant for children alone, but rather for ordinary people of all ages, "for to shewe to all maner of folk what maner of thing they ought to ensyeew and folowe" (p. 9).^[5] The books published in the following few centuries for children were didactic, meant for their spiritual and social edification, with little regard to the pleasures of reading. The hornbook (see Fig. 1), published

Fig. 1 Facsimile/replica of a Horn Book—printed by Otto Miller at Thomas Todd printing shop on Beacon Hill for the Horn Book, Inc. With permission.

between the sixteenth and mid-eighteenth centuries, consisted of the alphabet and a syllabary, as well as the Lord's Prayer. The battledore, a trifold piece of cardboard, which largely replaced the hornbook in the middle of the eighteenth century as paper became less expensive, included not only the alphabet and a syllabary, but also single words with woodcut images accompanying them and a brief verse or Biblical quotation. Grammars, books of manners, and religious tracts designed to induce children to lead virtuous, Christian lives, were the staple of seventeenth century English publishing. Much of this material was meant for the schoolroom, but some books, such as James Janeway's *A Token for Children, an Exact Account of the Conversion, Holy and Exemplary Lives of and Joyful Deaths of Several Young Children*, (1671–1672), were intended for children's leisure reading. Aesop's fables continued to be used as well, as one of the more entertaining ways of teaching, and were frequently republished with new morals. John Locke in 1703 first emphasized the importance of using Aesop with illustrations specifically meant for children to help them understand the meanings of the words and to entice them to a love of reading.^[5]

During the late seventeenth and early eighteenth centuries, folk and fairy tales became popular adult literature and influenced children's literature. The 12 volume *Arabian Nights Entertainment* or *One Thousand and One Nights* (*Mille et une Nuits*), known as *Alf layla wa layla* in Arabic, translated into French by Antoine Galland between 1704 and 1712, and into English between 1705 and 1716, was one of the most influential sources. This compilation of oral and written tales included philosophical, romantic, and even pornographic stories. "Aladdin," "Ali Baba and the Forty Thieves," and "Sinbad" as well as the frame story of Scheherazade have been most frequently retold for children. The stories influenced European writers, such as the German Wilhelm Hauff, to create their own "Oriental" stories. Even more influential were the artfully retold folk tales and literary fairy tales written by French upper class women, and some men such as Charles Perrault, who used them as a safe form of protest against both Louis the XIV's excessive taxation and the social conditions of marriage for women.^[6,7] Charles Perrault's 1697 *Histoire ou Contes du Temps Passé* popularly known as *Contes de ma Mère l'Ois* [Tales of My Mother Goose], translated into English in 1729, and Jeanne Marie le Prince de Beaumont's "La Belle et la Bête" (1756), translated into English in 1761 as "Beauty and the Beast," have remained popular as children's literature and were the sources of Disney's film adaptations. The popular title of Perrault's fairy tales collection, "Mother Goose," however, has been attached to nursery rhymes, rather than fairy tales, ever since John Newbery published *Mother Goose's Melody or Sonnets for the Cradle* (1765).

To obtain imaginative literature, seventeenth and eighteenth century children adopted adult books as their own.

The three most influential and popular of these were John Bunyan's *The Pilgrim's Progress* (1678), a Christian allegory with an adventurous plot; Daniel Defoe's *Robinson Crusoe* (1719), a celebration of middle class self-reliance; and Jonathan Swift's *Gulliver's Travels* (1726), a political and philosophical satire with a fantasy setting.^[5]

The chapbook was the main source of imaginative literature for children of the eighteenth century. Door-to-door peddlers, or chapmen, carried a variety of inexpensive wares, including these cheaply made folded paper books whose front page served as the cover and whose stories often ended where the paper had to be cut. Chapbooks, with their legends; medieval romances, including those of King Arthur; fairy tales, including stories from the Arabian Nights and Perrault; lurid true crime stories; jokes; and recipes, stimulated the imaginations of children such as the poet William Wordsworth, who had to read them surreptitiously because they were considered low class.^[8,9]

Active publishing for children began with John Newbery, a book publisher whose sideline of selling patent medicines allowed him to finance his venture into publishing for the children of the newly rising middle class. Newbery's *A Little Pretty Pocketbook* (1744), a small attractive illustrated book, is often credited with having been the first book for children. It was based on John Locke's educational philosophy of enticing children to learn through entertainment.^[5] (A facsimile of the first American edition of the book is available through the Library of Congress at http://lcweb2.loc.gov/cgi-bin/ampage?collId=rbc3&fileName=rbc0001_2003juv05880page.db.) Newbery's books include numerous editions of Aesop; the first comprehensive book of nursery rhymes, *Mother Goose's Melody* (1765); a series of informational books for children entitled *The Circle of Sciences* (1746–1748); and a didactic fictional book designed to improve children's morals, *The History of Little Goody Two-Shoes; Otherwise called, Mrs. Margery Two-Shoes* (1765), which some have attributed to Oliver Goldsmith.^[5]

It was not until the 1820s, after Jacob and Wilhelm Grimm's *Kinder-und-Hausmärchen* (1812), the first comprehensive collection of folktales, was translated from German into English as *German Popular Stories* (1823), with high quality engraved illustrations by George Cruikshank, that folk and fairy tales became accepted as literature for children in England. In Germany, these folktales became popular once the Grimms, seeing the success of their book in its illustrated English translation, had their brother Ludwig Emil Grimm add illustrations, and began to edit their collection to make the stories more readable for children. The Grimms also edited the fairy tales to suit German parents' expectations for teaching their children the virtues society considered important: obedience, hard work, orderliness, cleanliness, and piety.^[10] The Grimms' collection has been translated into more than 100 languages and the stories have entered the written as well as oral tradition of numerous countries throughout the world.

Many of the English-speaking world's stories, such as the familiar versions of "Hansel and Gretel" and "Rumpelstiltskin," now considered part of our heritage, were first introduced through the Grimms' fairy tales. Even more importantly, the Grimms inspired people all over the world to collect and retell their own folktales for children. Joseph Jacobs's *English Fairy Tales* (1898) has been particularly influential for English-speaking children's literature.

Throughout the nineteenth century, the debate continued over what constitutes good literature for children. Moral purpose remained important and imaginative literature began to be an important vehicle for inculcating positive values. Much of the literature of the beginning of the nineteenth century was didactic with thin storylines and characters whose only function was to demonstrate correct behavior, but by the second half of the nineteenth century imaginative literature began to have strong plots and memorable characters.

The literary fairy tale's popularity, begun in France in the seventeenth and eighteenth centuries, was greatly enhanced in the nineteenth century by the Danish Hans Christian Andersen and German writers such as E.T.A. Hoffmann, the author of "Nussknacker und Mauskönig" (1816) [*The Nutcracker and the Mouse King*, 1817]. Andersen, the author of *Eventyr, fortalte for børn* (1835–1842) [translated by Mary Howitt as *Wonderful Stories for Children*, 1846] used a lively, conversational style as well as memorable imagery to develop his themes through literary fairy tales such as "The Ugly Duckling" and "The Little Mermaid." Fantasy classics, such as James Barrie's *Peter Pan* (1906), best known for its stage version, and L. Frank Baum's *The Wonderful Wizard of Oz* (1900), elaborated on the tradition of literary fairy tales.

The nineteenth century also saw the birth of modern high fantasy with heroes fighting evil powers, often of mythic proportions, in the publication of George MacDonald's *The Princess and the Goblin* (1872) and *The Princess and Curdie* (1882). Although MacDonald had a moral agenda, he allowed children to discover his themes rather than stating them explicitly.^[11] By contrast, the primary purpose of Lewis Carroll's (pseudonym for Charles Dodgson) fantasy novels, *Alice's Adventures in Wonderland* (1865) and *Through the Looking Glass* (1872), was to give pleasure rather than to teach a moral. It is Carroll's playfulness, and to some extent subversive conspiracy between adult author and child reader against "the grown-ups," which marks a turning point in children's literature.^[12,13] While the subversiveness is minimal—in the end, Alice turns the cards upside down and returns to the ordered world of her family and school—most children's books, since *Alice*, have been taking the child's perspective, even as the child protagonist grows and ultimately resolves inner as well as external conflicts without the author resorting to providing explicit morals.

The last quarter of the nineteenth century and the first quarter of the twentieth century also saw the beginnings of another type of modern fantasy in which personified animals and toys explore themes of concern to children. Carlo Collodi's (pseudonym of Carlo Lorenzini) Italian classic, *Le avventure di Pinocchio* (1883), translated into English as *The Adventures of Pinocchio* (1892), follows a puppet's exploration of what it means to be human. Kenneth Grahame's animal characters, Rat, Mole, and Toad, in *The Wind in the Willows* (1908), explore friendships in an idyllic setting, while Rudyard Kipling's *The Jungle Book* (1894) and its sequel transport European and American children to "exotic" settings.

Fiction for children, especially the adventure novel, with its possible if not always plausible plots, was another development of the nineteenth century. Juvenile nineteenth century fiction was largely didactic, designed to inculcate duty, honor, kindness to the less fortunate, and decent treatment of animals, as in Anna Sewall's *Black Beauty* (1877).

Although fewer of the nineteenth and early twentieth century works of fiction for children have stood the test of time compared to fantasy, several of this era's books have become classics and continue to be read or remain a part of our culture through their film adaptations. Many children, for instance, are familiar with one of *Robinson Crusoe's* numerous offshoots, *The Swiss Family Robinson* (1814) [*Der Schweizerische Robinson* (1812–1813)] by the Swiss author Johann D. Wyss, through the Disney film, and some early twentieth century books, such as *Pollyanna* (1913) by Eleanor Porter, might have been forgotten, had it not been for their film versions.

Boys' adventures and domestic novels for girls dominated the market and children's reading. Boys' adventures were produced in both England and the United States, while girls' domestic novels tended to be more popular in America.^[14] Mark Twain's *The Adventures of Tom Sawyer* (1876), loosely based on the author's pre-Civil War era childhood experiences in Hannibal, MO, represents one of the most outstanding examples of the boy's adventure genre. It started a trend of adventure books about boys who get into scrapes, but are good at heart.^[15] *Huckleberry Finn*, (1885), with its social satire and complex themes continued the genre but took it to much greater heights, while avoiding didacticism. By contrast, Horatio Alger's *Ragged Dick; or Street Life in New York with the Boot Blacks* (1867) exemplified the didactic rags-to-riches urban adventure story.

Among the English adventure novels, the school adventures of Thomas Hughes' *Tom Brown's School Days* (1857) started a spate of British public (i.e., private) school-life stories; Robert Louis Stevenson's books, such as *Treasure Island* (1883), captured its readers through exciting plots, colorful characters, and exotic settings; and British author G. A. Henty's historical fiction, such as *With Clive in India* (1884), introduced historical fiction

and brought the countries of the British Empire into the homes of English and American children.

Louisa May Alcott's *Little Women*, (1868), which was the first of a series of books about Meg, Jo, Amy and their offspring (Beth having died in the first book), was one of the best of the domestic novels. Alcott's independent-minded girls and their strong mother can be seen as early feminists. Other girls' domestic series which were popular in the late nineteenth and early twentieth centuries, such as Margaret Sidney's (pseudonym for Harriet Lothrop, 1844–1924) immensely popular *Five Little Peppers and How they Grew* (1881), are known today mainly by their titles.

The redeeming power of the innocence of childhood, often combined with the idea of nature's restorative power, whether in its wilder state or in the cultivated garden, was a dominant theme of many of the most popular books of the late nineteenth, early twentieth centuries. Several of the best, with their strong plots, appealing characters, and a sense of place, continue to be published, read, and adapted to film and television. Swiss author Johanna Spyri's *Heidi* (1880, translated into English in 1884), set in the Swiss Alps, and English/American author Frances Hodgson Burnett's *The Secret Garden* (1911), set in an English garden on a country estate, epitomize the above themes. Canadian author L. M. Montgomery's *Anne of Green Gables* (1908) and its sequels, too, attained their popularity from their independent-minded yet innocent and loving protagonist, as well as from their picturesque and nostalgic setting.

Finally, the turn of the twentieth century saw in Edith Nesbit's books of realistic family fiction the introduction of a strong child narrator whose concerns are those of children rather than of adults. The children respond with intelligence, wit, and shrewd insight into the world of the adults, while continuing to maintain their innocence (p. 104).^[13] Nesbit's *The Railway Children* (1906) is still read and translated into other languages. The family adventure reached classic heights in Arthur Ransome's books of the Walker family's camping and sailing adventures in England's Lake District, starting with *Swallows and Amazons* (1930).

History of Illustration in Children's Books

Illustration has been used worldwide to convey information and tell stories throughout human history, from cave paintings to fourth century Chinese scrolls illustrating moral lessons of the Buddha, to medieval European stained glass windows, and Indian storytelling cloths used by village storytellers in India.

In illustrated books, although the text is dominant, the pictures capture significant moments in the narrative, often adding to characterization or setting. Book illustration in medieval Europe was primarily religious in nature and included illuminated manuscripts of The Bible as well

as prayer books such as the Duc de Berry's renowned "Book of Hours," *Les très riches heures* [The Very Rich Hours, often referred to as Book of Hours], (ca. 1424 A.D.) (See <http://www.ibiblio.org/wm/rh/>).

Woodblock printing made it possible to illustrate early printed books. William Caxton's 1484 *Aesop's Fables*, for instance, featured a picture of Aesop. Moravian minister John Amos Comenius's 1658 *Orbis Sensualium Pictus* [The World in Pictures] (see <http://www.mhs.ox.ac.uk/gatt/tower/catalog.asp?CN=40>), a picture encyclopedia, is often considered the first fully illustrated book for children. Comenius used illustrations to clarify and expand upon the text. It was not until the middle of the eighteenth century, however, that high quality illustrations began to be used in children's books, when John Newbery commissioned woodcut artists to illustrate his children's books. One of the finest among the late eighteenth–early nineteenth century woodcut artists, Thomas Bewick, was in much demand by the newly developing children's publishing trade throughout England, as was his brother John.^[5]

The development of metal engraving techniques in the late eighteenth and early nineteenth centuries made it possible to create more realistic images than those made with woodcuts. The mystical English poet William Blake illustrated his books using copper engraving and watercolors. George Cruikshank's illustrations for the Grimms' *German Popular Stories* (1823), translated by Edgar Taylor, provided detail and characterization unavailable in earlier illustrated books. Color began to be used in early nineteenth century alphabet books and nursery rhymes, although the colors had to be added by hand, often using child labor. By the 1860s and 1870s color printing using both woodblock and lithographic techniques, developed by the printer Edmund Evans, allowed artists such as Walter Crane, Randolph Caldecott, and Kate Greenaway to create full-color illustrated books.^[5] Some of the most enduring nineteenth century illustrations for children's books were by newspaper caricaturists and illustrators, such as John Tenniel, who immortalized the look of Alice and the other characters in Lewis Carroll's *Alice's Adventures in Wonderland* (1865) and *Through the Looking Glass* (1872), and the German Wilhelm Busch, creator of *Max und Moritz* (1865).

The turn of the twentieth century is often referred to as "The Golden Age of illustration." British illustrator Ernest H. Shepard created memorable characters for the *Wind in the Willows* (1908) by Kenneth Grahame (as well as for *Winnie-the-Pooh* (1926) and *The House at Pooh Corner* (1928) by A. A. Milne). French illustrator Maurice Boutet de Monvel with his delicate designs and colors influenced American children's illustrators.^[16] Arthur Rackham, a prolific illustrator from Britain, used strong lines and patches of light and shadows in his illustrations for children's books, including *The Fairy Tales of the Brothers Grimm* (1900), James Barrie's *Peter Pan in Kensington Garden* (1906), and *Mother Goose* (1913). Danish-born Kay Nielsen (*East of the Sun and West of*

the Moon, 1914 by Peter Asbjørnsen and Jorgen Moe) and French-born Edmund Dulac (*The Sleeping Beauty and Other Fairy Tales*, 1910 by Arthur Quiller-Couch) illustrated books in England for children and adults using delicate lines and romantic representations of palaces and clothes in an Art Nouveau style. American illustrator Howard Pyle retold and illustrated in black and white the legends of King Arthur and of Robin Hood at the end of the nineteenth century, while N.C. Wyeth created dramatic scenes in oil colors for adventure books such as *Treasure Island* (1911) by Robert Louis Stevenson. Although the ascendancy of picture books in wealthier countries seems to have supplanted illustrated books for children, illustrators of novels have continued to memorialize incidents and characters. A few of the illustrators who have created memorable characters using line drawings and halftones include Ilona Wikland (Pippi Longstocking); Pauline Baynes (Narnia series); Garth Williams (Little House series and Wilbur); Alan Tiegreen (Ramona Quimby); and Timothy Ering (Despereaux). Both Jerry Pinkney in *Tales of Uncle Remus* (1987) by Julius Lester and Barry Moser in *Jump!* (1986) by Van Dyke Parks and Malcolm Jones have provided new images for B'r'er Rabbit, and Moser has also created a new look for Alice.

PICTURE BOOKS

Definitions

The modern picture book format is a recent phenomenon, having been developed in the 1870s by British illustrators Kate Greenaway (1846–1901) and Randolph Caldecott (1845–1886). Greenaway's full-color illustrations for books such as *Under the Window* (1879), which consisted of original verse by Greenaway, depicted children playing in pastoral settings wearing light, airy clothes. Greenaway influenced both the depiction of children in picture books and children's fashions in the late nineteenth–early twentieth centuries.^[14] It was Caldecott, however, who created the first genuine picture books by providing characterization and setting as well as action-filled narrative through illustrations for each event in a nursery rhyme or story. He divided the text into 32 page segments, creating a parallel narrative through illustrations. Caldecott's skilled use of line to create dynamic images as well as his humorous interpretation of characters and events such as those for *Hey Diddle Diddle* (1883) (see Fig. 2) make his books classics. Beatrix Potter brought picture books to new heights by creating total unity between text and illustrations. She used expressive anthropomorphized animals, spare, naturalistic details, and plenty of white space to allow children to give scope to their imaginations, as in *The Tale of Peter Rabbit* (1901/1902), the picture book from the era that children most often continue to ask for.^[17]

Fig. 2 From *Hey Diddle Diddle and Baby Bunting* by Randolph Caldecott. London: Frederick Warne, n.d. original edition London: Routledge, 1883.

The two narratives of a picture book, textual and pictorial, encompass a wide range of interrelationships. The text may consist of one or two words or up to a long paragraph, usually written at a child's listening vocabulary level, but above his or her reading level, while the pictures may be simple, to match the single words or phrases meant for toddlers as in *Max's First Word* (1979) by Rosemary Wells, or they may be complex, adding a new dimension to the text. The parallel narratives of picture books—words and pictures—usually tell the same story, as in Tomie de Paola's *Strega Nona* (1975), with the pictures supporting every step of Big Anthony's misadventure. Frequently, however, the picture and text are even more integrated, neither being complete without the other, as in *Where the Wild Things Are* (1963) by Maurice Sendak and in *Officer Buckle and Gloria* (1995) by Peggy Rathmann, in which the pictures create dramatic irony. Sometimes the pictures are sufficient with few or no words, as in the case of *Tuesday* (1991) by David Wiesner. Generally, however, the complex relationship between image and text distinguishes picture books and creates the total reading/listening experience.

The Text of Picture Books

The traditional audience for picture books, children ages preschool through 7, is usually not expected to read the

text but rather to look at the illustrations while listening to the story, responding to both the verbal narrative and the pictures. The best of children's book authors do not speak down to their audience, but, like Kevin Henkes, the author/illustrator of Caldecott Medal and Honor winning books, they choose their words for effect, not for simplicity. In *Kitten's First Full Moon* (2004) Henkes describes Kitten's fall using carefully selected words and phrases of varied lengths: "But Kitten only tumbled-/ bumping her nose and banging her ear/ and pinching her tail./ Poor Kitten!" The phrase "Poor Kitten" serves as a refrain, giving the text rhythm. There are, however, picture books that are deliberately written with the child as beginning reader in mind, most notably Dr. Seuss's *Cat in the Hat* (1957); the Theodore Geisel Award honors those writers who are able to create varied and interesting language while adhering to a limited vocabulary.

Styles of Illustration in Picture Books

The primary function of the illustrations is to heighten emotional response through the use of color, line, shape, layout, texture, scale and point of view. Throughout the twentieth century, picture book artists experimented with the picture book format, while advances in technology also influenced picture book styles. Because of the cost

Fig. 3 From *YO! YES?* by Chris Raschka. Copyright © 1993 by Chris Raschka. Reprinted by permission of Orchard Books, an imprint of Scholastic Inc.

of full-color illustration before the 1960s, artists had to be creative to achieve their effects with few colors. Artists created award-winning picture books entirely in black and white, focusing on line, shape, and layout, as did Wanda Gág in *Millions of Cats* (1928); monochrome pictures of sepia or blue, as did Robert McCloskey in *Make Way for Ducklings* (1941) and *Blueberries for Sal* (1948); or with a few flat colors, as did Jean de Brunhoff in *Histoire de Babar, le petit éléphant* [*The Story of Babar*, 1931]; and H. A. Rey in *Curious George* (1941). The development of photographic offset printing eliminated the older, more tedious method, and the 1980s and 1990s brought further sophistication in color printing through the use of computers. Since the beginning of the 1980s there has been a trend toward more painterly oil and acrylic illustrations, such as Paul Zelinsky's images for *Rumpelstiltskin* (1986) with its shimmering scenes of golden straw. Artists, however, continue to use all of the earlier styles in combination with newer techniques. Mo Willems, for instance, used a few deft lines in *Don't Let the Pigeon Drive the Bus* (2003) to create Pigeon's expressions ranging from wheedling to sly to furious, and line work combined with touches of watercolor continues to be widely used, as for instance by artists Betsy Lewin in *Click, Clack, Moo: Cows That Type* by Doreen Cronin (2000) and Chris Raschka in *Yo! Yes?* (1993) (See Fig. 3). Increasingly, artists use computers to develop complex combinations of materials. Once electronic books become more accessible to the general public, artists are likely to take advantage of the computer's

capabilities for nonlinear sequencing with multiple linkages between scenes and actions.^[18]

Picture book artists use a wide range of art styles, some developing a signature style, others matching the style of a specific book to its subject, theme, or setting. Jerry Pinkney always uses an impressionistic style, as in Pat McKissack's *Goin' Someplace Special* (2001). Bryan Pinkney typically uses flowing lines and deep colors in scratchboard for subjects from folktales to biographies such as *Duke Ellington: The Piano Prince and His Orchestra* (1998) by Andrea Davis Pinkney. Cubist styles are reflected in some works of illustrators, including Christopher Myers's in *Harlem: A Poem* (1997) by Walter Dean Myers. Mixed media, combining collage and other media, such as paint in picture book illustration, pioneered by Ezra Jack Keats (*The Snowy Day*, 1962) and Leo Lionni (*Inch by Inch*, 1960), is used by many artists. Bryan Collier in *Uptown* (2000), for instance, created a tapestry of shapes and textures to depict Harlem (see Fig. 4). The influence of cartoon art is also apparent in many picture books, as for instance Ian Falconer's *Olivia* (2000) and Eric Rohmann's *My Friend Rabbit* (2002) (see Fig. 5).

Wordless Picture Books

Wordless picture books, which used to be an exception in picture book format, are increasing in numbers. These books rely entirely on the sequence of illustrations for their narratives. Some wordless books are designed to help young children interpret the visually told story through

Fig. 4 Illustration from *Uptown* by Bryan Collier. Copyright 2000 by Bryan Collier. Reprinted by permission of Henry Holt and Company.

carefully constructed sequences showing scenes of familiar actions, as in Australian author/illustrator Jan Ormerod's *Sunshine* (1981). Alexandra Day's *Good Dog Carl* (1985), a story about a Rottweiler and the toddler he baby-sits, is more fanciful and leaves greater leeway for interpretation by young readers. More sophisticated wordless books for somewhat older audiences include Jeannie

Fig. 5 Illustration from *My Friend Rabbit* by Eric Rohmann. Copyright 2002 by Eric Rohmann. Reprinted by permission of Henry Holt and Company.

Baker's *Home* (2004), which shows the passage of time in a city neighborhood; Mitsumasa Anno's *Anno's Journey* (1978), which is replete with cultural and historical allusions; David Wiesner's *Free Fall* (1988), an explorations of the boundaries between dream and reality; and Brian Selznick's *The Invention of Hugo Cabret* (2007), a 533 page historical fiction told through several hundred pages of images interspersed with some text. Other artist-storytellers who have told complex stories in wordless picture books include Russian artist Nikolai Popov in an antiwar book *Why?* (1996), and Belgian-born artist Gabrielle Vincent in *A Day a Dog* (1999), about a dog's quest for home.

Specialized Types of Picture Books: Alphabet Books, Counting Books, Concept Books, Engineered Books, and Graphic Novels

Traditionally alphabet books have introduced preschool children to the shapes and sounds of letters. Kate Greenaway's *A Apple Pie: An Old Fashioned Alphabet Book* (1886) has one concept for each letter. Well conceived alphabet books help develop phonemic awareness as children learn to hear and associate the sounds with the letters as well as the words (usually initial sounds) in which they appear as in Helen Oxenbury's *ABC of Things* (1972). Many alphabet books, however, go beyond direct representation to introduce new words and concepts, play with language, and stimulate visual perception and imagination. *Antics!* (1992) by Cathi Hepworth plays with language—An Einstein-like chemist ant illustrates “Brilliant”; *Animalia* (1986) by Graeme Base and *Alphabet City* (1995) by Stephen T. Johnson, evoke close observation; and Chris Van Allsburg stimulates the imagination as readers try to guess what fate may have befallen each letter of the alphabet, in *The Z Was Zapped: A Play in Twenty-Six Acts* (1987) (see Fig. 6).

Counting books may introduce the counting sequence and show a one-to-one correspondence between the numeral and the number of objects on the page, or they may cluster the images into groupings to match numbers, as does Anno's *Counting Book* (1975). Like alphabet books, counting books can be playful and stimulating. For instance, Czech artist Kveta Pacovska shows numbers doing acrobatic contortions in *One, Five, Many* (1990), and Bruce McMillan introduces fractions through photographs of children eating in *Eating Fractions* (1991).

Concept books introduce preschoolers to single concepts: (e.g. opposites, colors or shapes). Photographer Tana Hoban focused mostly on this genre, stimulating children to discover specific concepts and to look closely at the world around them, with books such as *Is it Larger, Is it Smaller* (1985) and *Shapes, Shapes, Shapes* (1986). Other award winning artists who create concept books include Donald Crews, Lois Ehlert, and Steve Jenkins.

Engineered books, books with tactile, three-dimensional, or moveable parts, have a long history. The first lift-the-flap book designed for children was Robert Sayer's *Harlequinade* (1765). Victorian engineered books included dial-turnable scenes as well as pop-up scenes. Lothar Moggendorfer in Germany created intricate pop-ups at the end of the nineteenth century. Due to the economic hardship of WWI and the Great Depression, the market for these elaborate books disappeared.^[19] Simpler engineered books, however, such as Dorothy Kunhardt's *Pat the Bunny* (1940) with fuzzy inserts and Eric Hill's *Where's Spot* (1980) with open-the-flap surprises continue to be enjoyed. Sophisticated engineered books are making a revival. Robert Sabuda's three-dimensional pop-ups and movable parts have greatly developed paper engineering, as in an adaptation of Baum's *The Wizard of Oz* (2000). Other contemporary pop-up artists of children's books include David Carter, Jan Pienkowsky, and Matthew Reinhart.^[20,21]

Influenced by both Western style comic books and by Japanese manga, graphic novels are book-length, self-contained works. Despite the term "novel," graphic novels represent every genre of literature, though they are best known for fantasy hero stories. Most graphic novels are written for young adults and adults. Many of the works

produced in graphic novel form are intellectually and emotionally challenging, as are Art Spiegelman's *Maus: A Survivor's Tale* (1986) and Marjane Satrapi's autobiographical *Persepolis* (2003), which captures a child's point of view about life in Iran before and during the 1979 revolution. Her theme, the use of ironic humor, and the haunting black and white images suggest a young adult and adult audience. Even when not emotionally challenging, the themes focus on young adult concerns such as romance or finding values to live by, as in *Garage Band* (2007) by Italian author/artist Gipi. Reading the text and pictures in a highly interactive way and interpreting the visual symbols are also sophisticated literacy skills.^[21,22] Graphic novels for young adults also include adaptations of classics, as, for instance, Peter Kuper's version of Franz Kafka's *Metamorphosis* (2003) and Stephane Heuet's adaptation of Marcel Proust's *Remembrance of Things Past: Combray* (2001).

Graphic novels for younger children include *The Greek Myths* (1991) by Marcia Williams; popular children's series such as Raina Telgemeier's adaptation of *The Babysitters Club* (2006) by Ann Martin; original modern fantasy such as Newbery Honor-winning writer Jennifer Holm's and artist-brother Matthew Holm's *Babymouse: Queen of the World* (2005) and other titles in the series; and biographies/autobiographies such as Michael Foreman's *War Boy: A Country Childhood* (1989) and Siena Cherson Siegel's account of her days at the Juilliard School in *To Dance: A Memoir* (2006).

Trends in Picture Books

Many picture books are for an older audience than the traditional preschool through 7 year old, or they are for multiple audiences of older and younger readers, because of their complex formats and allusions to other texts and visuals with which younger readers may be unfamiliar, as well as their use of sophisticated language. David Wiesner's *The Three Pigs* (2001), for instance, can be enjoyed on different levels by various ages; the youngest would likely enjoy seeing the pigs get away from the wolf while older children might understand the idea of moving in and out of stories and would be more likely to recognize the allusions. The dual audience for English author and illustrator Anthony Browne's *Willy the Dreamer* (1998) is distinct: while the daydreams of Willy, a chimp, about what he will do when he grows up are readily accessible to a young audience, the visual allusions are meant for adults familiar with both popular culture—Elvis Presley—and modern artists—René Magritte. Other picture books with sophisticated explorations of time and space include *The Red Book* (2004) by Barbara Lehman; *Black and White* (1990) by David Macaulay; and *Flotsam* (2006) by David Wiesner. Jon Scieszka's *The Stinky Cheese Man* (1992), illustrated by Lane Smith, is a book of fractured fairy tales, playing with the conventions of

story structure as well as a book's accustomed format. Australian author Margaret Wild's and illustrator Ann Spudvilas's *Woolvs in the Sitee* (2007) is a psychological exploration of fear. Frequently, picture books introduce subjects that require a sense of history or of social conditions usually considered beyond the cognitive and emotional level of preschool through first grade. Books like these include Peter Sis's *The Tree of Life: A Book Depicting the Life of Charles Darwin, Naturalist, Geologist, and Thinker* (2003); Emily Arnold McCully's *Bobbin Girl* (1996); Japanese author/illustrator Toshi Maruki's *Hiroshima No Pika* (1982); and Mary Williams's *Brothers in Hope: The Story of the Lost Boys of Sudan* (2005) illustrated by Gregory Christie.

For major English language picture book awards, see "Awards."

POETRY

Poetry for children differs from poetry for adults only in degree, not in kind—poets who write with children in mind select their words carefully, calling on the reader's/listener's emotional memory through description and imagery and creating sensory experiences through rhythm and devices of sound: rhyme, alliteration, onomatopoeia, etc. Children's poems focus on experiences and concepts of concern to children, from daily events like dealing with homework to questions about friendship, family, adult authority, and death. Delight in the immediate—the feel of mud, the taste of chocolate, the way it feels to swerve on a skateboard—are all likely themes in poems for children, as are emotions ranging from sibling rivalry to joy at a parent's return at the end of the day. Narrative poems might tell of humorous or dramatic events, or they might be biographical. Though children prefer humorous and accessible poems, they respond to a wide range of poetry if they hear or read it without being required to analyze it. Children can develop a love of poetry early in life.

If children are lucky enough to have heard lullabies, nursery rhymes, and folk songs, to have played to the accompaniment of street and game chants, then they come to the forms of poetry with a firm grasp of its bare bones—rhyme, rhythm, meter, and the *singingness* of language (p. 89).^[23]

The traditional nursery rhymes, or Mother Goose rhymes, are children's first poems. Even infants respond to the strong beat and predictable rhymes. Collections of nursery rhymes abound, their illustrations ranging from personified animals, as in Iona Opie's and Rosemary Wells's *My Very First Mother Goose* (1996) to contemporary urban settings, as in Nina Crews's *Neighborhood Mother Goose* (2004).

William Blake, the author of *Songs of Innocence* (1789) and of *Songs of Experience* (1794) whose poems "The Lamb" and "The Tyger" are frequently included in anthologies of poetry for children, was one of the first poets who wrote for children, though only his *For Children: The Gates of Paradise* (1793) explicitly stated the audience.^[24] Sir Isaac Watts, however, was better known in his own lifetime and throughout the nineteenth century. His gently didactic verses in *Divine Songs for Children* (1715) were a staple in homes and schools. During the eighteenth and most of the nineteenth centuries children also heard or read poems meant for an adult audience. These included folk ballads about Robin Hood. The chief form of poetry written deliberately for children was moral verse, which used rhythm and rhyme to help them remember lessons.^[5] Some of these verses, such as "Mary's Lamb" by Sarah Josepha Hale (1830) have passed into folklore. "A Visit from Saint Nicholas" by Clement Moore (1823) was one of the few poems for children that was written primarily for enjoyment during this era. Published as a book with Thomas Nast's illustrations in 1860, it influenced American images of Christmas^[13] and continues to be popular in many picture book versions. Other nineteenth and early twentieth century narrative poems republished as picture books include Robert Browning's *The Pied Piper of Hamelin* (1889), illustrated by Kate Greenaway (<http://www.indiana.edu/~librcsd/etext/piper/cover.html>) as well as by more recent illustrators; Henry Wadsworth Longfellow's "Paul Revere's Ride" (1860), illustrated by Christopher Bing (2001); and Alfred Noyes's "The Highwayman" (1902), illustrated by Charles Keeping (1981). Contemporary poets sometimes use narrative poems for biographies and informational books. Bobbi Katz celebrated American history through poems of varied styles to fit each topic in *We the People* (2000); Marilyn Nelson wrote *Carver: A Life in Poems* (2001) as well as *A Wreath for Emmett Till* (2005); and Carmen T. Bernier-Grand portrayed Frida Kahlo in *Frida: Viva la vida! Long Live Life!* (2007).

Edward Lear's verses were perhaps first in a long line of English language nonsense poetry, designed to amuse through imaginative juxtaposition of incongruities and through language play. Many of Lear's limericks are included in children's anthologies, and his "The Owl and the Pussycat" (1870) has appeared frequently as a picture book, including one by James Marshall. Laura Richards was one of the first Americans to publish nonsense verse: her "Eletelephony" in *Tirra Litra: Rhymes Old and New* (1932) is a classic. Poets throughout the twentieth century who have played with nonsense verse for children as well as adults include Dylan Thomas, John Ciardi, and Theodore Roethke. Some contemporary practitioners of the art include X. J. Kennedy (*Exploding Gravy: Poems to Make You Laugh*, 2002); Dennis Lee (*Alligator Pie*, 1974), J. Patrick Lewis (*July is a Mad Mosquito*, 1994), and Jack Prelutsky (*Scranimals*, 2002). Where nonsense

verse ends and humorous poetry begins is hard to determine. Well known poets such as David McCord, Russell Hoban, Karla Kuskin, and Douglas Florian continue to play with the English language—"Just when you think you know the boa/ there's moa and moa, and moa, and moa." (from *Beast Feast*, 1994 by Douglas Florian). Shel Silverstein's (*Where the Sidewalk Ends*, 1974) great popularity rested on his ability to make everyday experiences, from watching TV to taking out the garbage, seem hilarious. These and other poets also look at serious topics from a humorous angle. Jane Yolen's "Homework" (from Michael Hearn's *Breakfast, Books, and Dreams*, 1981) pokes light-hearted fun at excuses, and Eve Merriam's socially ironic poems combine wordplay and social commentary on topics ranging from alienation in a technological world to war.

While children respond most readily to humorous and narrative poems in the early years, even the youngest can respond to the musicality of lyrical poetry, such as that of two early poets who wrote for children: Christina Rossetti, *Sing Song: A Nursery Rhyme Book* (1871) and Robert Louis Stevenson, *A Child's Garden of Verses* (1885). By the middle elementary grades children also appreciate lyrical poetry in which the author speaks of personal experiences without nostalgia or condescension. The reader is invited to see through the poet's eyes the familiar in a new way, as in Aileen Fisher's and Valerie Worth's nature observations and Patricia Hubbell's vision of the modern world: "Concrete mixers are urban elephants/their trunks are raising a city" from *8 A.M. Shadows* (1965). The reader might realize that the poet has put words to a familiar experience: Lillian Morrison, who has specialized in sports poetry, captures the moment of "flow" when the player becomes one with his or her activity in "The Sidewalk Racer or On the Skateboard" (*The Sidewalk Racer*, 1977); Myra Cohn Livingston describes a child's fear in "The Dark" (*Worlds I know and Other Poems*, 1985); and Eloise Greenfield tells about things an urban child delights in, from the gushing of a fire hydrant, a "flying pool," to cuddling in her mother's arms in "Honey, I Love" (*Honey, I Love and Other Love Poems*, 1977).

Concrete poems wittily represent the meaning of the words through the layout of the text. In *Flicker Flash* (1999), poet Joan Graham laid the words out in the form of the subject of the poem: for instance, a birthday cake. J. Patrick Lewis's *Doodle Dandies* (1998), Paul Janeczko's *A Poke in the I: A Collection of Concrete Poems* (2001), illustrated by Chris Raschka, and John Grandits' *Blue Lipstick* (2007) offer a variety of concrete poems for children and young adults.

Poetry for young adults, in keeping with their need for identity development, often uses a first person perspective to speak of love and loneliness, doubts, and dreams. Paul Janeczko writes of being a young teen in his working class neighborhood in *Brickyard Summer* (1989), and Gary Soto in *Neighborhood Odes* (1992) shares both universal

experiences of love and longing, and those more specific to his experience as a Latino teen. Mel Glenn in *Class Dismissed!* (1982) and Nikki Grimes in *Bronx Masquerade* (2002) use a first person perspective to express young people's hurts and hopes.

Sources for identifying outstanding poets for children include anthologies by Catherine Clinton, Beatrice Schenk de Reniers, Stephen Dunning, Donald Hall, Lee Bennett Hopkins, X. J. Kennedy, Paul Janeczko, Nancy Larrick, Bruce Lansky, Myra Cohn Livingston, Lilian Moore, Naomi Shihab Nye, Jack Prelutsky, and Michael Rosen, as well as the National Council of Teachers of English Award for Poetry for Children, <http://www.ncte.org>.

TRADITIONAL LITERATURE

Storytelling seems to be integral to the human experience. Traditional stories were used to educate and acculturate children and adults to the mores and values of their society as well as to entertain and to express a group's hopes and wishes. Charles Perrault's eight fairy tales artfully retold in *Histoire ou Contes du Temps Passé* (1697), established the popular notion that folktales are for young people. The idea was solidified with Jacob and Wilhelm Grimm's retelling of German folktales in *Kinder-und-Hausmärchen* (1812). Today children throughout the world learn the traditional stories of their culture as well as those of other cultures through books, though storytelling continues to survive.^[25]

In many countries traditional literature represents the bulk of publishing for children; even in countries with a large children's publishing industry, such as Australia, Japan, the United Kingdom, the United States, and Western European countries, a large proportion of picture books are retellings of fables, folktales, myths, and legends. The influence of traditional stories in every culture goes beyond the publishing of traditional literature: original stories too, whether in picture books or in fiction and fantasy for older readers, as well as in film and even advertising, draw on the structures, themes, and characters of traditional stories.^[17,26]

Traditional literature published for children tends to fall into the categories of fables, folktales, myths and legends. Fables are didactic stories. They are brief and often use animal characters to teach ethical lessons that help hold society together. In the most familiar of fables, the Aesop fables, the morals are usually stated at the end. Though less well-known in the West, the fables of India, the Panchatantra and Jataka, are becoming available through picture book versions. Because of the brevity of Aesop's fables, collections of fables are particularly enjoyable and have been reissued with different artists' interpretations, such as those of Jerry Pinkney (2000); Tom Paxton with Robert Rayevsky's illustrations (1988); and Lisbeth Zwerger (1989). Reinterpretations or

humorous modern versions include Leo Lionni's *Frederick* (1967); Arnold Lobel's *Fables* (1980); and Toni and Slade Morrison's *The Ant or the Grasshopper?* (2003), illustrated by Pascal Lemaitre. Two collections of Panchatantra tales retold for children include Gloria Kamen's *Ringdoves* (1988) and Asha Upadhyay's *Tales from India* (1971). Demi in *Buddha Stories* (1997) and Jeanne M. Lee in *I Once Was a Monkey: Stories Buddha Told* (1999) have produced collections of the Jataka tales. For a collection of international fables, see *Feathers and Tails: Animal Fables from Around the World* (1992) retold by David Kherdian.

Folktales serve a variety of functions, from teaching lessons to entertainment. Folktales are about ordinary people and anthropomorphized animals, and include a range of story types. Fairy tales or wonder tales delight listeners and readers with their courageous and often kind heroes who achieve extraordinary goals through perseverance and the good sense to listen to wise advice offered by magical helpers. Fairy tale heroes who win through patience and kindness characterize the hundreds of worldwide variants of kind-and-unkind sisters and related Cinderella stories, many of which have been retold in picture book format. A few of these are *Yeh-Shen: A Cinderella Story from China* by Ai-Ling Louie (1982); the Korean *Kongi and Potgi* by Oki Han (1996); *The Irish Cinderlad* by Shirley Climo (1996); and the Russian *Baba Yaga and Vasilisa the Brave* by Marianna Mayer (1994). The equally ubiquitous questing hero, who wins the prize through courage, perseverance, and usually magical help, is featured in stories such as *Song Bird* (1999) from Africa by Tololwa Mollel; *Inch Boy* (1986) from Japan by Junko Morimoto; and *The Black Bull of Norway* (2001) from Scotland by Charlotte Huck.

"Pourquoi" or "why" tales, which purport to explain how a custom, plant, or other observed phenomenon came to be, often used to teach children how they should behave, and cumulative or chain stories, characterized by events repeating themselves in longer and longer chains, are especially popular with children. Native American stories are rich in pourquoi tales such as Gayle Ross's *How Turtle's Back Was Cracked* (1995). Pourquoi tales are also told in Africa, as in Ashley Bryan's "How the Crab Got his Shell" in the collection *Turtle Knows Your Name* (1989). "The Gingerbread Boy," with its many picture book variants such as *The Pancake Boy* (1988) by Lorinda Cauley, is a cumulative tale, as is *Too Much Talk* from Ghana, retold by Angela Medearis (1995). Humorous tales, whether of numbskulls or of tricksters, are told for entertainment, as negative exemplars, or as a way to express a group's belief in the possibility of survival against the odds. Some popular numbskulls and tricksters include the Appalachian Jacks, most famously collected by Richard Chase in *The Jack Tales* (1943) and more recently retold by Gail Haley in *Mountain Jack* (1992); the West African and Caribbean Ananse as in *Ananse and*

the Lizard: A West African Tale (2002) by Pat Cummings, and *First Palm Trees: An Anancy Spiderman Story* (1997) by James Berry; the Native American Coyote (or Rabbit or Iktomi or Raven, depending on the region) as in *Ma'ii and Cousin Horned Toad* by Shonto Begay (1992); the Puerto Rican Juan Bobo as in *Juan Bobo* (2000) by Marisa Montes; the Goha from Arab-speaking countries as in *Goha, the Wise Fool* (2005) by Denys Johnson-Davies; and The Hodja from Turkey as in *Watermelons, Walnuts, and the Wisdom of Allah and Other Tales of the Hoca* (1967, 1991) by Barbara Walker. Though some popular tall tales are not true folktales, they are nevertheless part of American lore. Steven Kellogg's retellings with amusing illustrations include *Paul Bunyan* (1984) and *Pecos Bill* (1986). In *Cut from the Same Cloth* (1993) Robert San Souci retells tall tales about American women, some historic, others folkloric. Illustrated collections of international folktales and collections of specific countries, regions, or ethnic groups abound. Some of the resources for identifying the best of these collections include professional textbooks listed under "Bibliography," while individual stories in collections can be found through Margaret Reade MacDonald's *The Storyteller's Sourcebook: A Subject, Title and Motif Index to Folklore Collections for Children, 1983–1999* (2001), Joseph Sprug's *Index to Fairy Tales* (1994), as well as this index's earlier editions by Norma O. Ireland and by Mary Huse Eastman.

Every culture has its myths, stories that give concrete expression to their belief systems. Best known in the West are the Greek and Roman myths. The D'Aulaires' *Book of Greek Myths* (1962) and Alikì's *The Gods and Goddesses of Olympus* (1994) introduce 8–11 year olds to the Greek pantheon, while William Russell retells the stories in a lively collection *Classic Myths to Read Aloud* (1989) with pronunciations and explanations of common words derived from the myths. Less known are the Norse myths, which have been retold by authors such as Kevin Crossley-Holland in *Axe-Age, Wolf-Age: A Selection of Norse Myths* (1985) and Mary Pope Osborne in *Favorite Norse Myths* (1996). Native American myths have been retold in several collections by Joseph Bruchac, including in a science activities book by Michael Caduto, *Keepers of the Earth: Native American Stories and Environmental Activities for Children* (1989; 1999). John Bierhorst, a folklorist, has retold North, Central, and South American myths for children in books such as *The Mythology of Mexico and Central America* (1990). Chinese-Canadian artist Song Nan Zhang has retold Chinese myths of origins in *Five Heavenly Emperors* (1994), and English-Indian author Debjani Chatterjee has retold the Hindu myths in *The Elephant-Headed God* (1989). Virginia Hamilton's *In the Beginning: Creation Stories from Around the World* (1988), and Steven Zeitlin's *The Four Corners of the Sky: Creation Stories and Cosmologies from Around the World* (2000) are two of many international collections of myths. Bible stories have been retold by outstanding authors such

as Miriam Chaikin, Tomie de Paola, Peter Dickinson, Erik Kimmel, Julius Lester, Jan Mark, Geraldine McCaughrean, and Martin Waddell.

Legends are told as history, whether of the exploits of a group's hero, of important events in the history of the group itself, or of a symbolic animal, plant, landmark, or object of importance to the group.^[27] Legendary heroes embody the ideals of their societies. Children's books about legendary heroes include *The Epic of Gilgamesh* (2003) by Geraldine McCaughrean; *Black Ships Before Troy: The Story of the Iliad* (1993) by Rosemary Sutcliff; *The Adventures of Odysseus* by Neil Philip (1996); *Sundiata: Lion King of Mali* (1992), as well as *Golem* (1996) by David Wisniewski; *John Henry* (1994) by Julius Lester; and *The Magical Monkey King: Mischief in Heaven: Classic Chinese Tales* (2002) by Ji-Li Jiang. Legends of places and plants in North America are retold in Joseph Bruchac's *Between Earth and Sky: Legends of Native American Sacred Places* (1996).

Traditional literature offers an introduction to cultures around the world. Whether retold by people from the tales' culture of origin or someone outside the culture, authors and artists should treat the material with respect, avoid trivializing it, research the background of the story, credit their sources, and indicate in what way they may have altered it from its traditional origins according to storytellers Betsy Hearne^[28] and Joseph Bruchac.^[29]

REALISTIC FICTION

Fiction, though presenting imaginary characters and situations, can be realistic. The author creates a world which is simpler than real life, but the events, characters, and settings are within the realm of the possible in the natural world, even if at times they stretch the reader's credulity. Two subcategories of realistic fiction are Contemporary Fiction and Historical Fiction.

Contemporary Fiction

Contemporary fiction deals with characters who live contemporaneously with the author and the author's initial readers. In 1868, when Louisa May Alcott's *Little Women* was published, her readers were familiar with the events, the language, and the concerns of the characters. In the same way, today's contemporary fiction has relevant themes for today's young readers, as well as realistic plots, characters, settings, and dialogue. Dialogue that includes the latest in slang may date the work; outstanding contemporary fiction, however, transcends through theme, plot, and characterization, the limitations imposed by language, while adding, over time, a historical element the author did not originally intend. By minimizing setting and avoiding the most up-to-date slang, some contemporary fiction maintains its currency for 30 or 40 years, as have

Beverly Cleary's early books which were written in the 1950s and 1960s (*Ramona the Pest*, 1968).

Two of the major changes since the nineteenth century have been the degree of social realism and the tone authors use. Themes of personal development or coming of age and relationships within the family, with peers, and within the larger society continue to dominate children's fiction, but children's problems and the perspectives presented tend to be more complex and diverse than in early twentieth century fiction. While in British author Arthur Ransome's *Swallows and Amazons* (1930) the children develop their skills and demonstrate their ingenuity and courage during a sailing adventure in the idyllic setting of the Lake District in England, the skill and courage the protagonist of *The Wanderer* (2000) by Sharon Creech demonstrates as she sails with her adoptive family across the Atlantic must be matched by her courage in search of her identity. The family that meant a safe haven for children in earlier fiction, as in Eleanor Estes's *The Moffats* (1941), today may be the source of conflict. Parents remarry and children and stepparents may not get along, as in *My War with Goggle-Eyes* (1989) by British author Anne Fine; children may be abandoned by one or both parents, as in *A Catalogue of the Universe* (1985) by New Zealander Margaret Mahy, or dumped on a frail grandparent, as in *The Same Stuff as Stars* (2002) by Katherine Paterson; or a child may have to deal with abuse, as in *What Jamie Saw* (1995) by Carolyn Coman and in *I Hadn't Meant to Tell You This* (1994) by Jacqueline Woodson. Other themes of social realism include teens struggling with drug addiction, as in *A Hero Ain't Nothin' But a Sandwich* (1973) by Alice Childress, and *Smack* (1998) by British writer Melvin Burgess; AIDS, as in *Eagle Kite* (1995) by Paula Fox; homelessness, as in *Stone Cold* (1993) by British author Robert Swindell; coming to terms with homosexuality, as in *Deliver Us from Evie* (1994) by M. E. Kerr; and illegal immigration, as in *Ask Me No Questions* (2006) by Marina Budhos—in short, the issues of concern to adults and young people at the time of writing. In spite of the serious tone and subject of many of these books, however, the underlying themes are personal growth, the redeeming power of caring for others, and hope.

Humorous treatments of families and their struggles or of children and their peers continue to play an important part in engaging children with life issues. Barbara Park's *Junie B. Jones* series and British author Hilary McKay's Casson family series, starting with *Saffy's Angel* (2002), have children consider everything from learning to fit in at school to searching for one's identity; Canadian Polly Horvath's ever-optimistic hero's misadventures make children laugh in *Everything on a Waffle* (2001); a teen whom everyone else has given up on finds self-respect and a sense of purpose as a foster child in a riotously creative family in *Surviving the Applewhites* (2002) by Stephanie Tolan; and a child's yearning for a mother is poignantly

and humorously told in *The Higher Power of Lucky* (2006) by Susan Patron. Humor has also lightened the tone in books dealing with serious social issues, such as fear of homelessness in *Money Hungry* (2001) by Sharon Flake, and protecting the environment in *Hoot* (2003) by Carl Hiassen.

Adventure and survival in nature also continue as important subjects of fiction. Wilderness adventures, such as *Hatchet* (1987) by Gary Paulsen, provide children a chance to vicariously test their ingenuity and mastery of their environment, as do urban adventures, such as Cornelia Funke's magic realistic adventure *The Thief Lord* (2002) set in Venice. Urban adventures, however, can also have much more serious themes, as in *The Planet of Junior Brown* (1971) by Virginia Hamilton, in which Junior Brown is introduced to the world of squatter children in New York City.

Besides increased social realism and a more serious tone, point of view has become more complex since the 1960s. Young adult author Paul Zindel pioneered the telling of a story from multiple or unusual perspectives in *The Pigman* (1968).^[30] Since then authors have frequently used the technique, especially in books for young adults, as in *Nothing But the Truth* (1991) by Avi in which an unreliable narrator tells us about his "unfair" treatment by a teacher; in *Monster* (1999) by Walter Dean Myers, in which a teen arrested for acting as an accessory to a robbery ending in murder examines himself through a pretend camera lens; and in Virginia Walter's *Making Up Megaboy* (1998), which shows the reactions of the parents, only friend, the media, classmates, the victim's widow, and, finally, the young perpetrator to a deadly shooting.

Historical Fiction

In historical fiction authors set the action in the past, usually after doing research, in order to create an authentic setting, with the characters' concerns and language fitting the era depicted. Historical fiction, like contemporary fiction, is realistic. It too sheds light not only on the era in which it is set but also on contemporary times, as the stories frequently deal with issues of concern at the time of writing. Katherine Paterson's *Lyddie* (1991), set in a textile factory town in the 1830s, for instance, explores the issue of child labor which is still relevant in some parts of the world. Besides introducing a historic era, the authors usually explore universal themes such as the quest for personal identity or questions of honor, loyalty, friendship, and death. There is almost no limit to the historic settings that authors have attempted to evoke for young people, but certain eras are particularly well represented, as for instance the European Middle Ages in the books of Karen Cushman, Eric Haugaard, and British author Rosemary Sutcliff. The American Civil War and slavery are also frequently explored as in Patricia Beatty's *Charley*

Skedaddle (1987) and *Turn Homeward, Hannahlee* (1984); Sharon Draper's *Copper Sun* (2006); Paul Fleischmann's *Bull Run* (1993); Joyce Hansen's *Which Way Freedom* (1986); and Maureen Stack Sappey's *Letters from Vinnie* (1996). World War II and its aftermath can be seen from multiple perspectives. Many of the books have been translated from other languages. Settings include: Denmark (Bjarne Reuter's *The Boys from St. Petri*, 1994); Germany (Peter Härtling's *Crutches*, 1988); Greece (Alki Zei's *Petros' War*, 1974); Japan and Korea (Yoko Kawashima Watkins's *So Far from the Bamboo Grove*, 1986); Korea (Linda Sue Park's *When my Name Was Keoko*, 2002); Netherlands (Els Pelgrom's *The Winter When Time Was Frozen*, 1980); the United Kingdom (Nina Bawden's *Carrie's War*, 1973); and the United States (Mary Downing Hahn's *Stepping on the Cracks*, 1991 and Patricia Rielly Giff's *Lily's Crossing*, 1997). The Holocaust and its context have been treated by many European and American authors including in titles such as *Daniel Half Human and the Good Nazi* by David Chotjewitz and *Friedrich* (1970) by Hans Peter Richter, both set in Germany; *Run, Boy, Run* (2003) by Uri Orlev, set in Poland; and *Upon the Head of the Goat* (1981) by Aranka Siegal (1981) as well as *Marika* (2002) by Andrea Cheng, both set in Hungary.

The Civil Rights era has been portrayed in books such as *The Watsons Go to Birmingham, 1963*, (1995) by Christopher Curtis, which begins with the humorous interactions of an African American family and their journey South, but turns serious during the trip, with sibling rivalry and teasing replaced by siblings helping each other survive emotionally. The Great Depression has been frequently depicted from various perspectives: *Esperanza Rising* (2000) by Pam Munoz Ryan, from a Mexican-American immigrant farm worker perspective; *Out of the Dust* (1997) by Karen Hesse from an Oklahoma farm girl's perspective; and *Bud, Not Buddy*, (1999) by Christopher Curtis from an African American perspective. Successful works of historical fiction have believable characters, vivid and accurate settings, and plausible plots.

MODERN FANTASY

Fantasy is one of the most enduring forms of children's literature. Only poetry and the genre's closest forebears, the traditional folk-fairy tales, legends, and myths have persisted longer, and for some of the same reasons. By transcending specific geographic settings and symbolically representing ideas, authors have been able to speak to audiences across both time and space.

Modern fantasy contrasts with its folkloric antecedents by its complexity, highly developed themes, and carefully crafted characters, many of whom are, in spite of the fantasy element, recognizable young people in search of identity, friendships, and values to live by. It was Tolkien

who articulated the essential quality a fantasy writer must strive for if the reader is to achieve “willing suspension of disbelief.” Tolkien called for consistency based on the “laws” set up for the imagined world and for treating the magic seriously, not as something to explain away or to smirk at.^[31]

Some of the typical categories of fantasy include literary fairy tales, which are halfway between traditional folktales and modern fantasy; high fantasy or quest fantasy; animal fantasy; toy fantasy; enchanted journeys and alternative worlds; supernatural and time-shift fantasy; and science fiction.

Contemporary authors of literary fairy tales for children include the American novelists Robin McKinley (*Beauty*, 1978 and *Rose Daughter*, 1997—both a reenvisioning of Jeanne-Marie Leprince de Beaumont's 1757 classic “Beauty and the Beast”); Gail Carson Levine (*Ella Enchanted*, 1997—a psychological exploration of the Cinderella figure); Donna Napoli (*The Magic Circle*, 1993—a look at the witch's perspective in Hansel and Gretel); and Jane Yolen who is sometimes referred to as the American Hans Christian Andersen. Literary fairy tales continue to draw on traditional fairy tale characters such as elves, dragons, princesses, wizards and witches, etc. as do works of high fantasy, also referred to as quest fantasy.

The high fantasy genre whose heroes begin life inauspiciously but prove their nobility through valor, perseverance, and the willingness to fight against the forces of evil—begun by George MacDonald in the nineteenth century—continues strong in the twenty-first century. The international popularity of the Harry Potter series by J. K. Rowling, starting with *Harry Potter and the Philosopher's Stone* (1997, i.e., *The Sorcerer's Stone*) has rekindled interest in the genre, partly because though the evil is of mythic proportions, Harry is a less-than-perfect, seemingly ordinary boy who defeats the embodiment of evil by relinquishing the temptations of power, choosing through love to save his companions and ultimately the world. With a few exceptions, high fantasy with its complex plots, often strange secondary-world settings, literary allusions, and symbolism is generally more accessible and of greater interest to upper elementary students through adults than to younger readers. A few of the American award-winning writers of high fantasy include Lloyd Alexander whose Welsh mythology-inspired Prydain series (beginning with *The Book of Three*, 1964) presents adventurous male and female heroes as well as humorous secondary characters; British-born Susan Cooper (*The Dark is Rising* series, starting with *Oversea, Under Stone*, 1965, in which contemporary children protect the land as they communicate with Arthurian heroes); Ursula Le Guin whose *Earthsea* series (*A Wizard of Earthsea*, 1968) begins with a 12-year old boy wizard and ends six volumes later with a young adult female hero in *Tehanu* (1990); and Robin McKinley who has created strong female heroes in books such as *The Blue Sword* (1982).

A few of the many great British fantasy writers since the mid-twentieth century include C. S. Lewis (*The Chronicles of Narnia* series, starting with *The Lion, the Witch and the Wardrobe*, 1950, a Christian allegory in which four ordinary children must choose between Aslan, the good king of Narnia and the evil white witch); Diana Wynne Jones (*The “Chrestomanci”* series, 1977–2005 about a young boy magician, his sisters, and their schooling); and Philip Pullman (*Northern Lights*, 1995, i.e., *The Golden Compass* and the rest of His Dark Materials series), whose male and female protagonists explore complex issues of belief, the uses of technology, and issues of power). International writers of high fantasy whose works have been translated into English include German author Michael Ende (*Die Unendliche Geschichte*, 1979, i.e., *The Neverending Story*, 1983); Italian author Silvana De Mari (*L'Ultimo Elfo*, 2004, i.e., *The Last Dragon*, 2006); and Japanese author Miyuki Miyabe (*Bureibu sutori*, 2003, i.e., *Brave Story*, 2007).

Animal fantasy has dominated picture books since Beatrix Potter first dressed Peter Rabbit in a blue jacket and gave him a sense of adventure. Because preschoolers readily identify with the animal protagonist, authors/illustrators can focus on universal feelings and can have animals do more extreme and more dangerous activities than would be realistic for young children. This last consideration is also true for the animal fantasies written for early elementary age children, such as Beverly Cleary's *The Mouse and the Motorcycle* (1965). Most animal fantasy is for younger readers, but some, because of their complexity and literary allusions, are more likely to appeal to middle and upper elementary age students than to younger children: *Mrs. Frisby and the Rats of NIMH* by Robert O'Brien (1971); *Watership Down* (1972) by Richard Adams; *Redwall* (1987) and its series by Brian Jacques; and *The Amazing Maurice and His Educated Rodents*, (2001), by Terry Pratchett.

Since Carlo Collodi's Pinocchio first strove to become human in 1883, toys in children's books have been talking about their feelings, making friendships, and discussing philosophical questions of what it means to be loved (*The Velveteen Rabbit*, 1922 by Margery Williams Bianco); how to be a friend (*Winnie-the-Pooh*, 1926 and *The House at Pooh Corner*, 1928 by A. A. Milne); and whether it is better to take your chances with life or to be the perfect manufactured object (*Alexander and the Wind-up Mouse*, 1969 by Leo Lionni). While books about toys are usually written for younger children, books such as Russell Hoban's *The Mouse and His Child* (1967), replete with social commentary, appeal to somewhat older children.

Alice's Adventures in Wonderland (1865), with its combination of playfulness and satire, set a high mark for journeys to a parallel universe. In some books it is the children of this world who find a way to the alternative world, as in *The Phantom Tollbooth* (1961) by Norton Juster; *Coraline* (2002) by Neil Gaiman; and *Dangerous*

Spaces (1991) by Margaret Mahy. In other stories it is the inhabitants of the parallel world who slip into our world, as in *The Borrowers* (1952) by Mary Norton and in *Moorchild* (1996) by Eloise McGraw. Or, the story takes place entirely in what Tolkien called a secondary world, as in Diana Wynne Jones's *Cart and Cwiddler* (1975) and the rest of the Dalemark quartet and Terry Pratchett's *Wee Free Men* (2003) and all of the books in the Discworld series.

Time slip/time travel is often a device for introducing historical eras or to help a protagonist get in touch with people in the past in order to understand their perspectives or to understand themselves better, as in *Playing Beatie Bow* (1980) by Australian author Ruth Park, who takes a modern-day girl back to her grandmother's days in late nineteenth century Sidney, and *The Ultimate Game* (2000) by Christian Lehmann, in which three boys discover that war is not a game. Other time slips include *Tom's Midnight Garden* (1958) by British author Philippa Pearce; *Building Blocks* (1984) by Cynthia Voigt; *The Devil's Arithmetic* (1988) by Jane Yolen; and *If I Should Die Before I Wake* (1994) by Han Nolan.

Many children and young adults like tales of haunting, horror, and the supernatural in both traditional literature and in modern fantasy, as the popularity of Stephen King with adolescents attests. Tales of the supernatural for elementary school age children include: *The Improbable Cat* (2004) by Allan Ahlberg; *The Children of Green Knowe* (1954) and its sequels by Lucy Boston; *The Ghost of Thomas Kempe* (1973) by Penelope Lively; *The Ghost Drum* (1987) by Susan Price; *Whispers in the Graveyard* (1994) by Theresa Breslin; as well as the humorous spoof of the genre, *Bunnicula* (1979) by Deborah and James Howe.

Some fantasy works are hard to classify. A few of these include modern classics such as Natalie Babbitt's philosophical *Tuck Everlasting* (1975) with its exploration of death and the cycle of life; Roald Dahl's *James and the Giant Peach* (1961) and *Charlie and the Chocolate Factory* (1964); Alan Garner's *The Owl Service* (1967); and Geraldine McCaughrean's *A Pack of Lies* (1988).

Science fiction, while less generally popular with children than fantasy, has its enthusiastic followers.^[14] Jules Verne (*Vingt Mille Lieues sous le Mers* 1870, i.e., *20,000 Leagues Under the Sea*) and H. G. Wells (*The Time Machine*, 1895) introduced the genre. Since its inception, science fiction, though based on scientific and technological concepts, is speculative rather than accurate, dealing with technological possibilities as well as their social ramifications. Madeline L'Engle in *A Wrinkle in Time* (1962) with its contemporary settings and technological dystopia explores the concept of free will within the contexts of both a totalitarian government and Christian theology. Other works of science fiction address issues such as the meaning of civilization (*The Green Book*, 1981 by Jill Paton Walsh); the uses and abuses of cloning people

(*House of the Scorpion*, 2003 by Nancy Farmer and *Galax-Arena*, 1992 by Gillian Rubinstein); and what it would mean if we could eliminate pain, sorrow and even the memories of painful history from our lives (*The Giver*, 1993 by Lois Lowry). Other authors who have written science fiction for children and young adults include Monica Hughes, Andre Norton, Kenneth Oppel and William Sleator.

INFORMATIONAL BOOKS AND BIOGRAPHIES

Although children's informational books are not a new genre—John Newbery published many informational books, including the series *The Newtonian System of Philosophy* (1761) by “Tom Telescope,” changes in attitudes toward children and changes in publishing technology have fueled a dramatic increase in engaging, quality informational books for children.

Changes in attitudes toward children involved viewing them as capable of responding to the inherent interest of factual material without the need for a thin story veneer, formerly thought essential in order to fascinate young readers. The use of a story line to introduce informational material, however, does remain common for preschoolers through first or second grade, and research suggests that the emotional involvement with the story characters helps these children remember the information.^[32] One of the most successful among informational books with a story line is the *Magic School Bus* series by Joanna Cole, illustrated by Bruce Degan, in which the author and illustrator make use of fantasy by having the magic school bus explore a wide range of scientific concepts from the inner world of the circulatory system to the eye of a hurricane. Most outstanding authors of informational books, however, have chosen to eschew fictionalizing even for younger children in favor of using an engaging style. They involve readers by stimulating their thinking through demonstrating the process of research, asking provocative questions, and leaving unanswered questions for children to ponder and dream about researching in the future. Vivid photographs, diagrams, and images extend the information. Jean Fritz, in a series of biographies for 2–4th graders about American Revolutionary War figures (*And Then What Happened Paul Revere?* 1973) pioneered the use of a lively, informal style of writing while adhering to strictly documented information and presenting a balanced view of her subjects, flaws included, in order to help her readers realize that they too can strive to be great. When Fritz chose accuracy over idealized models, she broke new ground in writing biography for children. Judith St. George (*So You Want to be President*, 2000) and Kathleen Krull (*Lives of the Musicians: Good Times, Bad Times, and What the Neighbors Thought*, 1993) have continued in the same vein.

Writing informational books for children is challenging, as another outstanding writer, Russell Freedman

(*Lincoln: A Photobiography*, 1987 and numerous other award winning books) has written,

I welcome the discipline of a book such as that [history or biography] imposes on the author. It is something like writing a sonnet: your words must fit within a certain format, and every word counts . . . The art lies in the selection and arrangement of documented facts, in the closely observed and painstakingly constructed narrative, and in the imposition on those facts of the author's unique sensibility. It requires a feat of imagination as well as diligent research to make the past live again for the reader. (p. 25)^[33]

Imagination and diligent research are certainly the hallmarks of the best of informational books, along with the advantage of high quality photographic reproduction at affordable prices. Freedman, for instance, specializes in using reproductions of archival photographs, letters, diaries, and other primary documents to enhance readers' understanding of his subjects.

Similar to biography and history, the presentation of science for children has also undergone a major change, the field having particularly benefited from technological developments. Children's books feature photographs from the field, as well as electron microscopic, satellite, and fiber-optic images. As with biography and history, ideas about what constitute good science informational books for children have changed in the last quarter of the twentieth century. Newer children's science books focus on the processes of science as well as on science concepts and discoveries, thus involving readers in the painstaking but exciting work of scientific research. Patricia Lauber's *The News About Dinosaurs* (1989) is an example of this approach: she presents the reader with established scientific information about dinosaurs, then shows how, because of new research evidence, these beliefs had to be reevaluated. Similarly, Susan Quinlan involves the readers in both science concepts and processes as she presents 12 rain forest ecology mysteries in *The Case of the Monkeys that Fell from the Trees* (2003), and Sy Montgomery and Nic Bishop document the work of field scientists in books such as *Quest for the Tree Kangaroo: An Expedition to the Cloud Forest of New Guinea* (2006).

Even before children are ready to think formally about hypothesis testing, trade books introduce them to the scientific method, involving them in observation and classification. Following the lead of Milicent Selsam, a science teacher and writer during the 1950s and 1960s whose works stimulated preschool and early elementary school age children to observe their world and to develop hypotheses about their observations, science writers/artists such as Jim Arnosky (*Crinkleroot* nature series) and Steve Jenkins (*What Do you Do with a Tail Like This?* 2003), engage children through biological and visual puzzles. Others have young children consider factorials (Masaichiro and Mitumasa Anno in *Anno's Mysterious*

Multiplying Jar, 1983) and very large numbers (David Schwartz in *How Much is a Million?* 1985). Informational books also deal with other topics. For instance, they play with language (Fred Gwynne, *A Chocolate Moose for Dinner*, 1976); make grammar and punctuation lessons fun (Lynne Truss's *Eats, Shoots, and Leaves: Why Commas Really Do Matter*, 2006, which is based on her book for adults, *Eats, Shoots, and Leaves: The Zero Tolerance Approach to Punctuation*); or explain to children a range of personal experiences.

It is impossible here to convey the variety of informational books and biographies available to children and young adults; however, the following recommended book lists provide a beginning for exploring the many outstanding authors and illustrators, and their works.

- "Best Science Books for Children" named annually by *Science Books and Films* a publication of the American Association for the Advancement of Science
- "Notable Trade Books for Young People" by the National Council for the Social Studies/ Children's Book Council. This extensive list is published every May in the association's journal *Social Education*, or order directly from Children's Book Council. Also at NCSS: <http://www.ncss.org/resources/notable/>
- "Outstanding Science Trade Books for Students K-12" by National Science Teachers Association, Children's Book Council. This extensive list is published every March in the association's journal *Science and Children*, or order directly from Children's Book Council. Also at NSTA: <http://www.nsta.org/publications/ostb/>

See also "Awards" for major informational book and science trade book awards.

INTERNATIONAL CHILDREN'S LITERATURE

International books are defined as having been written in another country for the readers of that country, and then imported and made available either in the original language or in translation. The nineteenth and early twentieth centuries produced classics that readers in many countries consider their own, regardless of the books' origins: The Grimms' and Hans Christian Andersen's fairy tales; *Alice's Adventures in Wonderland*; *Pinocchio*; Jules Verne's books; *Heidi*; *Tom Sawyer*; *The Wonderful Wizard of Oz*; *Winnie the Pooh*; *The Story of Babar*; and *Pippi Longstocking*. With the exception of such classics, however, relatively few children's books are truly international, the worldwide success of English author J. K. Rowling's Harry Potter (1998–2007) series being a rare exception. Furthermore, children in English-speaking countries are exposed to few translated books, with imports representing 1% of the total output of children's books per year as compared with Germany or Japan,

where translated books represent around 30% of children's publishing.^[2] Reading international books, however, is important as they give children a more balanced view of their world than do the news and commercial films, open a window to the lives of children whose experiences are different from theirs, and connect children to each other through shared readings.^[2]

Because children's books from Australia, Great Britain, Canada, the United States and New Zealand are more readily available than translated books, this section will focus on translated books. (For awards from English-speaking countries, see "Awards" section).

In spite of the challenges, it is possible to identify books that were first published in non-English speaking countries. Awards lists highlight authors and illustrators who are known in many countries. The most important award for international literature is the Hans Christian Andersen Award given by the International Board on Books for Young People (IBBY, <http://www.ibby.org/index.php?id=273>). Margaret Mahy of New Zealand (2006), whose works range from picture books to young adult fiction and fantasy, represents the breadth and quality of writing of the winners. Some of the other recipients who are known worldwide include Finnish author Tove Jansson, who created the Moomintroll family, Swedish author Astrid Lindgren with her irrepressible Pippi Longstocking, and Irish author Martin Waddell, who has written many tender picture books such as *Can't You Sleep Little Bear?* (1988) as well as retellings of legends and contemporary fiction. The award is an excellent way to become acquainted with writers and illustrators from other countries such as Brazilian authors Lygia Bojunga Nunes and Ana Maria Machado; Japanese illustrator Sukeichi Akaba; Norwegian author Tormod Haugen and French illustrator Tomi Ungerer. (Six Americans have also received the award.) The works of most of the awards recipients are available in English.

The Mildred L. Batchelder Award (<http://www.ala.org>) is an important resource for outstanding translated books available in the United States. While earlier winners of the Batchelder award tended to be translations from Germanic-speaking countries—Denmark, Germany, Netherlands, Norway, Sweden^[34]—in more recent years awards have gone to Brazilian, French, Israeli, Italian, Japanese, Spanish, and Turkish authors as well.

The Batchelder Award books have included all genres, but they are especially rich in historical fiction. The stories have been set in Renaissance Italy in *The Apprentice* (1993) by Pilar Molina Llorente; Napoleonic era Germany in *Innocent Soldier* (2005) by Josef Holub; and 1950s Syria in *Hand Full of Stars* (1990) by Rafik Schami. Most frequently represented, however, has been the time period just before, during and right after World War II, including the Holocaust, making the Batchelder Award winners a good source for studying this historic era from multiple perspectives (specific titles are discussed in the section on "Fiction.").

Batchelder winners also include lighthearted books and books set in the present. Some genres and topics include works of contemporary fiction such as the serious yet also humorous exploration of friendship and its healing power in *The Friends* (1996) by Japanese author Kazumi Yumoto; fantasy, such as *Rabbit Island* (1978) by Swiss author Jörg Steiner, an allegory of freedom; and science fiction, such as *Konrad* (1977) by popular Austrian author Christine Nöstlinger about what it means to be human.

Some of the best ways to identify high quality children's books that were first published in another country which are available in the United States are through the three annotated bibliographies sponsored by the United States Board on Books for Youth (USBBY): Carl Tomlinson, *Children's Books from Other Countries* (1998); Susan Stan, *The World Through Children's Books* (2002); and Doris Gebel, *Crossing Boundaries with Children's Books* (2006). (See "Bibliography"). Other international children's book awards are also listed under "Awards."

The following are additional sources for discovering international authors/illustrators and their works:

- Books available in English in the United States: USBBY's "Outstanding International Books" annual list, posted at <http://www.usbby.org>.
- The "IBBY Honour List," published biennially at the IBBY Web site (under Activities) at <http://www.ibby.org/>, lists the best written, illustrated, and translated book of each member nation.
- IBBY's journal, *Bookbird*, provides insight into the national children's literatures of different countries.
- *White Ravens*, an annual annotated list of international books compiled at the International Youth Library (Internationale Jugend Bibliothek) in Munich available at the International Children's Digital Library (<http://www.icdlbooks.org/servlet/WhiteRavens>).
- The International Children's Digital Library <http://www.icdlbooks.org/index.shtml>, full text digitized children's books in their original languages.

LITERATURE REPRESENTING DIVERSE PERSPECTIVES

Readers need to encounter both windows showing the lives of others and mirrors reflecting themselves.^[35] Literature written by and about nonmainstream groups is essential to accomplishing this. This entry will focus primarily on multicultural books, that is, books of underrepresented ethnic groups, but will also discuss children's literature that deals with disabilities and alternative sexual orientation.

Multicultural Books

For multicultural literature to be successful, authors must be able to portray the culture of the ethnic group

authentically, based on familiarity with the cultural nuances, whether through intimate personal experience or through intensive research.^[36] While most librarians and other educators agree that books presenting diverse perspectives are important, building a multicultural collection continues to be a challenge. The Cooperative Children's Book Center (CCBC) at the University of Wisconsin, Madison, reported in 2007 that of the approximately 5000 children's trade books published annually in the United States, five percent (5%) of the books had significant African American or African content, 2.9% having been created by African American authors or illustrators. The numbers were even smaller for other nonmainstream ethnic groups, with 1.3% of the books having Native American content and only 0.4% having been created by Native American authors or illustrators.^[37]

The Coretta Scott King Award (<http://www.ala.org>) has been instrumental in highlighting the works of outstanding African American authors and illustrators. Themes range from the universal to the culturally specific. Recurrent themes include developing relationships and a positive self concept, as in picture books by Eloise Greenfield (*Nathaniel Talking*, 1988, illustrator Jan Spivey Gilchrist) and Angela Johnson (*When I am Old With You*, 1990, illustrator David Soman); a sense of history and pride in the accomplishments of famous and unsung African Americans, as in the books of Tonya Bolden, James Haskins, and Patricia and Frederick McKissack; and realistic portrayals of the struggles of contemporary young people, as in the works of Sharon Draper, Sharon Flake, Walter Dean Myers, and Jacqueline Woodson. The illustrators who have received the award include, among many others, artists mentioned in earlier sections, such as Gregory Christie, Bryan Collier, Floyd Cooper, Leo and Diane Dillon, Christopher Myers, Brian Pinkney, and Jerry Pinkney. For an extensive annotated bibliography, see Rand and Parker's *Black Books Galore* (in "Bibliography").

While most of the approximately 2.2% of children's books representing Asian Americans are folktales, there are many authors and illustrators who portray Asian American experiences realistically, although Chinese or Japanese Americans are best represented among both authors and subjects.^[38] Striking a balance between striving for acceptance by the mainstream culture through assimilation and maintaining ethnic identity have been dominant themes in contemporary and historical fiction as in many of Laurence Yep's books, such as *Child of the Owl* (1971); Gene Luen Yang's *American-Born Chinese* (2006); Cynthia Kadohata's *Kira, Kira* (2004); An Na's *A Step from Heaven* (2001); Tanuja Hidier Desai's *Born Confused* (2002); and the picture books *Apple Pie 4th of July* (2002) by Janet Wong, and *Halmoni and the Picnic* (1993) by Sook Nyul Choi. Many books also celebrate cultural heritage, as in Kam Mak's *My Chinatown: One Year in Poems* (2002), Grace Lin's *Year of the Dog*

(2006), and Madhur Jaffrey's *Seasons of Splendor* (1985). The Asian Pacific American Award for Literature (<http://www.apalaweb.org/awards/>) honors authors and illustrators who portray Asian or Asian-American culture authentically.

Latino/Latina authors and illustrators portray the diversity of experiences in Latin American countries and U.S. Latino communities. George Ancona's, Monica Brown and Raul Colon's, and Carmen Lomas Garza's informational picture books document both daily lives and the lives of famous people; the narrative poetry of Carmen T. Bernier-Grand and Margarita Engle celebrate historical and contemporary figures while the lyric poems of Francis X. Alarcon, Juan Felipe Herrera, Pat Mora, and Gary Soto give voice to children's experiences; and Francisco Jimenez, Pam Muñoz Ryan, and Victor Martinez portray through autobiography and fiction the importance of family and the challenges of being poor and an immigrant. While much of Latino/Latina children's literature is specific to Mexican American experiences, Alma Flor Ada and Lulu Delacre are two of the authors who also portray Cuban and Puerto Rican culture and folklore. Three awards that recognize outstanding Latino books include The Pura Belpré Award (<http://www.ala.org>), the Americas Award (<http://www.uwm.edu/Dept/CLACS/aa/index.html>), and the Tomás Rivera Award (<http://www.education.txstate.edu/departments/Tomas-Rivera-Book-Award-Project-Link.html>)

Until recently most children's books about Native Americans were written by non-Native writers. Even when well-meant, these books' themes, characterizations, details of everyday life, and values were and often still are inauthentic.^[39] Increasingly, there are children's books in all genres created by American Indian writers and illustrators. Besides retelling traditional legends and myths, Joseph Bruchac (Abenaki) for instance, has written picture books (*Fox Song*, 1993), fiction (*The Heart of a Chief*, 1998), and modern fantasy (*Skeleton Man*, 2001). Other authors, such as National Book Award winner Sherman Alexie (Spokane/Coeur d'Alene) and Cynthia Leitich Smith (Muscogee) show the lives of contemporary Native Americans through realistic fiction while Louise Erdrich (Ojibwe) and Tim Tingle (Choctaw) have provided Native American perspectives on historic eras and events through historical fiction. Sources for authentically written/illustrated books about Native American experiences include: The online catalog of Oyate, <http://www.oyate.org>, a non-profit Native American organization; *A Broken Flute: The Native American Experience in Books for Children* (2005) by Doris Seale and Beverly Slapin (See "Bibliography"); and the American Indian Youth Literature Award <http://aila.library.sd.gov/News/2008youthlit/index.htm>. (See "Awards").

Finding books representing Middle Eastern Americans or Muslims is a particular challenge, but children's books written by Middle Eastern Americans are beginning to

appear. Naomi Shihab Nye has written about Palestinian Americans' experiences visiting family in Palestine in picture books such as *Sitti's Secret* (1994) and in contemporary fiction such as *Habibi* (1997) and has translated Arabic poetry for young people. Nye's books of poetry and anthologies express hope for a peaceful world. Other writers describe refugee experiences, as do Ibtisam Barakat in *Tasting the Sky* (2007); Deborah Ellis, a Canadian author, in *The Breadwinner* (2000) and its sequels; and Rukhsana Khan in a picture book, *The Roses in my Carpets* (1998).

For reviews of current multicultural books, see:

MultiCultural Review, the official publication of EMIERT, the Ethnic and MultiCultural Information Exchange Round Table of the ALA. <http://mcreview.com/>

For annotated bibliographies, see "Bibliography"

Books about Children with Special Needs

In the nineteenth century children with disabilities were presented in children's books as exemplars of virtue, often acquired by the child after developing the disability. Sentimental and unrealistic presentations continued in the twentieth century though a few children's books did present children with disabilities realistically, focusing on not only their struggles but their strengths. *Johnny Tremain* (1943) by Esther Forbes is an early example. The Schneider Family Award of the ALA (<http://www.ala.org>), begun in 2004, was established in order to recognize books of literary/artistic quality that present the disability experience, whether of the protagonist or of the family. Disabilities can be physical, mental, or emotional, such as Cynthia Lord's *Rules* (2006) about an autistic boy and his older sister, Pam Muñoz Ryan's *Becoming Naomi León* (2004) about a Mexican American girl and her learning disabled brother, and Pete Seeger and Paul DuBois Jacobs's *The Deaf Musicians*. Another excellent resource, especially for younger children, their families, and teachers is a 300 item bibliography compiled by Crystal and Kaiser (2007) (see "Bibliography").

Books Featuring Gay, Lesbian, or Transgendered Characters

Few picture books for children feature homosexual protagonists or same-sex parents. Of the few, Justin Richardson and Peter Parnall's *And Tango Makes Three*, a picture book account of two male penguins in a New York City Zoo raising a penguin chick, is one of the best picture books on the topic of same-sex households. There are far more well-written young adult books with gay or lesbian characters by writers like Nancy Garden, Julie Peters, Alex Sanchez, and Ellen Wittlinger. The best of the books feature characters who are not defined solely by their sexual identity. The "Stonewall Award," listed in

ALA-Awards (<http://www.ala.org>) recognizes children's books dealing with gay/lesbian/transgendered issues.

NONPRINT MEDIA

Children's literature has long been tied to toys, decorative objects, and other products, such as children's dishes and linens, the best known of which may be those depicting Beatrix Potter's characters. While most of these products are commercial ventures, libraries have made good use of the puppets and dolls that have been created from literary characters, such as Madeline, The Cat in the Hat, and The Wild Things, to generate interest in the books.

The new forms of media that changes in technology have made possible have added to rather than supplanted books as a source of children's literary experiences. Besides original films meant for children, children's classics, such as *Little Women*; *Heidi*; *Pinocchio*; and *The Secret Garden* have been adapted to film, most several times, in both live action and animation, and are available through videotapes/DVDs and Web-based film sources. One of the films made from a children's book that has achieved classic status in its own right is *The Wizard of Oz* (Dir: Fleming, 1939). A few of the many more recent award-winning children's books with film adaptations include *Bridge to Terabithia* by Katherine Paterson; *Charlie and the Chocolate Factory* by Roald Dahl; *Ella Enchanted* by Gail Carson Levine; the *Harry Potter* series by J. K. Rowling; *Holes* by Louis Sachar; *The Polar Express* and *Jumanji* by Chris Van Allsburg; *A Wrinkle in Time* by Madeline L'Engle; and many of Dr. Seuss's books, including his *How the Grinch Stole Christmas*. Some children's books, such as *Anne of Green Gables* by L. M. Montgomery; *Carrie's War* by Nina Bawden; *Sarah, Plain and Tall* and its Sequels by Patricia MacLachlan; and *Konrad* by Christine Nöstlinger have been made directly into television movies. The International Movie Database, <http://www.imdb.com> is a good source for identifying different productions of these films.

Besides commercial film and television, several producers have used film/video to recreate picture books, as close to the original as possible. These productions preserve the original text and art, adding animation or iconography, music, narration, and sound effects. These formats are available in school and public libraries and are meant primarily for preschool and elementary age children. Weston Woods Studios pioneered the format and set the standard for painstaking effort to make possible for classroom sharing the literary and visual delights of a picture book. The Andrew Carnegie Medal (<http://www.ala.org>) honors the producers of an outstanding children's video. Award-winning videos range from iconographic images of picture books such as Mordecai Gerstein's *The Man who Walked Between the Towers* (2005), produced by Michael Sporn and Paul Gagne, to live action such as

Jump in Free Style (2007), produced by Kevin Lafferty, directed by P. Hoen. Children's videos are reviewed in *School Library Journal* and *Booklist*.

Audiobooks have moved with the technology from vinyl records to cassette tapes to compact discs and have gained a far wider audience, as adults and young adults have begun to listen to audiobooks. High quality children's and young adult books are available in audio format. Because the quality of narration is important, audiobooks are reviewed in such professional journals as *Horn Book Magazine*, *School Library Journal*, *Booklist* and *VOYA* (*Voice of Youth Advocates*). Three major awards for audiobooks are: the Audie Award (<http://www.hbook.com/resources/awards/default.asp>), the *Audiobook Hall of Fame* (<http://www.hbook.com/resources/awards/default.asp>) and the Odyssey Award from Association for Library Services to Children (ALSC) and Young Adult Library Services Association (YALSA) divisions of ALA (<http://www.ala.org>). Award-winning audiobooks may be read by a full cast, as in *Knuffle Bunny* (2006) which was read by author Mo Willems and his family, but more often are narrated by a single narrator with occasional musical accompaniment as in 2008 Odyssey Award winning *Jazz* (2007) by Walter Dean Myers.

Electronic books, also referred to as e-books or digital books, are becoming increasingly important for reference work for high school students and adults, but children's trade books, while available in digital form since the mid-1990s, have not yet become widely popular. Nevertheless CD-ROM and online digital versions exist and are reviewed in *School Library Journal*. The best of the e-books take advantage of computer animation and use it to enhance the text and allow children to interact with the medium, as is the case with David Macaulay's *The New Way Things Work*, Version 3.2 (DK, 2007). Most electronic books, even the better ones, however, make limited use of the technology. The potential for great changes to the delivery method of picture books and novels is only beginning to be realized, but picture book artists, such as Jean Gralley, are excited about the possibilities of "lifting the book off the page" and onto portable, rollable, back-lit and searchable e-paper which will have the advantages of both the book and digital technology.^[18]

Another use of electronic texts, accessibility from anywhere, is already a reality. Besides digital archives of historical children's books from university and national libraries, The International Children's Digital Library (<http://www.icdlbooks.org/>) is a growing collection of electronic texts which allows readers to access full-text books from a wide range of countries. Most of the books are in-copyright books that authors and publishers have made available to children worldwide, but the digital library also includes historic nineteenth and early twentieth century books.

Computer games with sophisticated graphics which allow multiple players to interact in virtual environments

have become a major form of "literature" as players become creators of realistic contemporary or futuristic worlds as in *Sims 2*. The realistic visuals allow players to better immerse themselves in the worlds they are exploring, while the roles they build allow them to look at the ramifications of the decisions they make within the game.^[40]

CHILDREN'S LITERATURE AWARDS, ORGANIZATIONS, AND COLLECTIONS

Children's literature research collections have burgeoned nationally and internationally since the mid-twentieth century, when an ALA survey identified 153 collections in the United States and Canada. In 1995, there were over 300 American collections, and 119 collections internationally. National libraries have comprehensive collections, and their catalogs can be accessed online. The International Federation of Library Associations (IFLA) provides links to National Library Catalogues (<http://www.ifla.org/VI/2/p2/national-libraries.htm#U>). Two of the oldest international research collections include the International Youth Library in Munich (<http://www.ijb.de/>) and the International Institute for Children's Literature, Osaka (<http://www.iiclo.or.jp/english/english.htm>). For other major collections and research centers identified by country, see the International Children's Literature Research Society's Web page (<http://www.irscl.com/>). Besides links to collections, the society's Web page also lists journals of children's literature.

The following Awards list identifies organizations and their children's book awards. Because of space limitations it is not possible to identify all national awards; the list was therefore limited to English Language and major international awards. The Database of Award Winning Children's Literature compiled by Lisa R. Bartle provides access to award winning books by author, title, and subject (<http://www.dawcl.com/>).

International Awards:

Swedish Arts Council

The Astrid Lindgren Memorial Award.

(http://www.alma.se/default_a.aspx?id=247&epslanguage=EN) : Given for a *body of works*,

living authors, illustrators, storytellers and promoters of reading are eligible. Annual, started 2002.

International Board on Books for Young People. (<http://www.ibby.org/> see Activities)

Hans Christian Andersen Award: for a *body of works* (total contribution to children's literature) by an internationally acclaimed author; total work by international illustrator (two different awards). Every 2 years, started 1956.

International Reading Association (<http://www.ira.org>)

Children's and Young Adult's Book Awards for author's first or second publication. Fiction and nonfiction

for primary, intermediate, and young adult readers. (Annual, since 1975)

U.S. Awards:

American Institute of Physics. (<http://www.aip.org/aip/writing/winchild.html>)

Science Writing Award—Children (Annual since 1988) by the ALA—Association for Library Services to Children (<http://www.ala.org/ala/alsc/awardsscholarships/awardsscholarships.cfm>)

Andrew Carnegie Medal for Excellence in *Children's Videos*. Annual, started 1991.

Caldecott Medal: for best *illustrated picture book* by U.S. illustrator (citizen or resident). Annual, started 1938.

Laura Ingalls Wilder Award: for a *body of works* by U. S. author or illustrator. Every 3 years, started 1954.

Mildred L. Batchelder Award: Given by the ALA to the U.S. publisher of the *best-translated book* of the previous year, which had been originally published in another language. Annual, started 1968.

Newbery Medal: for best *written children's book* by U.S. author (citizen or resident). Annual, started 1922.

Odyssey Award for *audiobooks*. Annual, started 2008.

Pura Belpré Award given jointly with REFORMA for a *Latino/Latina author and illustrator*. Annual, started 1996.

Robert F. Sibert *Informational Book* Medal: Annual, started 2001.

Schneider Family Book Award for authors or illustrators of outstanding books that depict the *disability experience* for grade school, middle school, teens. Annual, started 2007.

Theodore Seuss Geisel Award for most outstanding *beginning reader trade books for authors and illustrators*. Annual, started 2004.

American Library Association Ethnic and MultiCultural Information Exchange Round Table (<http://www.ala.org/ala/emiert/corettascottkingbookaward/corettascott.cfm>)

Coretta Scott King Award and Honor books: best written text by an *African American writer*, best picture book by an *African American illustrator*. Annual, started 1970.

Asian/Pacific American Library Association an ALA Affiliate (<http://www.apalaweb.org/awards/awards.htm>)

Asian Pacific American Awards for Literature. Children's categories include authors and illustrators of an outstanding book of fiction or nonfiction that is related to *Asian/Pacific Heritage*, not necessarily by someone of that heritage. Annual, started 2004.

Boston Globe-Horn Book Awards (<http://www.hbook.com/bghb/>)

Picture book, Fiction, Nonfiction category by *The Boston Globe* and *Horn Book Magazine*. Annual, started 1967.

Center for Latin American and Caribbean Studies. University of Wisconsin, Madison

The Americas Award. (<http://www.uwm.edu/Dept/CLACS/aa/index.html>)

U.S. works of fiction, poetry, folklore, or selected non-fiction (from picture books to works for young adults) published in the previous year in English or Spanish that authentically and engagingly portray *Latin America*, the *Caribbean*, or *Latinos in the United States*. Annual, started 1993.

Jane Addams Peace Association (<http://home.igc.org/~japa/index.html>) and Women's International League for Peace and Freedom (WILPF).

Jane Addams Children's Book Awards

The award is given for "children's books published the preceding year that effectively *promote the cause of peace, social justice, world community and the equality of the sexes and all races* as well as meeting conventional standards for excellence." Annual, started 1953.

National Council of Teachers of English (<http://www.ncte.org>)

Award for Excellence in Poetry: Every 3 years, started 1977

Orbis Pictus Award: For an outstanding *informational book* (including biography) of the previous year. Annual, started 1990.

Texas State University College of Education. (<http://www.education.txstate.edu/departments/Tomas-Rivera-Book-Award-Project-Link.html>)

Tomas Rivera Mexican American Children's Book Award. Honors authors and illustrators who create literature that depicts the *Mexican American* experience. Annual, started 1995.

The Horn Book Magazine Web page (<http://www.hbook.com/resources/awards/default.asp>) lists a wide variety of national and international children's media awards, including the *National Book Award*; *The Golden Kite Award*; the *Audie* for Audiobooks, the *Audiobook Hall of Fame* and the *Will Eisner Award* for comic books and graphic novels.

British Awards:

Chartered Institute of Library and Information Professionals (CILIP) <http://www.carnegiegreenaway.org.uk/home/index.php>

Carnegie Award to the *author* of best children's book first published in the United Kingdom (or copublished within three months) the previous year. Annual, started 1937.

Kate Greenaway Award to the *illustrator* of the best children's book first published in the United Kingdom (or co-published within three months) the previous year. Annual, started 1955.

Australian Awards:

Children's Book Council of Australia, in the categories of *older readers, younger readers, early childhood, picture book* and *informational book*. Annual. <http://cbca.org.au/>

Canadian Awards:

Canadian Council for the Arts, Governor General's Literary Awards: in seven categories, including

Children's literature (text) and Children's literature (illustration) <http://www.canadacouncil.ca/prizes/ggla/>

Canadian Library Association <http://www.cla.ca> "CLA at Work"-Awards-Book Awards

Book of the Year for Children Award for *text*. Annual, started 1947

Amelia Frances Howard-Gibbon Award for *Illustrator*. Annual, started 1971

Young Adult Canadian Book Award. Annual, started 1981.

New Zealand Awards:

Library and Information Association of New Zealand <http://library.christchurch.org.nz/Kids/LiteraryPrizes/> EstherGlen/

Esther Glenn Award for the most distinguished contribution to *children's and young adult* literature. Annual, started 1945.

Children's Services in Libraries

Virginia A. Walter

Department of Information Studies, University of California, Los Angeles, Venice, California, U.S.A.

Melissa Gross

School of Information, Florida State University, Tallahassee, Florida, U.S.A.

Abstract

Children's services in libraries began at the end of the nineteenth century in the United States and were well institutionalized by the 1950s. Service to children birth to age 12 or 14 is now understood to be a standard element of public library operations. This entry looks at the nature of those services, the education and work of children's librarians, and some emerging challenges and issues. The focus is on contemporary services to children in the United States. However, a brief discussion of international approaches to the field is also provided.

INTRODUCTION

On a typical day, more than a third of the people who enter an American public library are children under the age of 14. They arrive in strollers and on skateboards. They come to hear stories; find a book to read; get help with homework; play games; make things; borrow a device, such as an iPad or e-reader; or use the computers. The lucky ones find a glorious space especially designed to appeal to young people with professional librarians available to help them meet their needs that day. All of them will find a basic level of service that is an affirmation of the vision of the women who developed the concept more than 100 years ago.

This entry will outline the historical development of library service to children and describe how it is implemented today. It will look at the role of the children's librarian in providing that service and discuss some of the more urgent challenges facing them today—the increasing diversity of their clientele, rapidly changing information and communication technology, and the pressure to document the outcomes of their services. Finally, it will look briefly at some of the international dimensions of library service to children.

HISTORY

Children were not welcome in the first public libraries in the United States. The philanthropists and civic leaders who established these institutions in the early 1800s intended to provide uplifting literature to adults who were unable to purchase their own books. They also wanted to help newly arrived immigrants assimilate to the American way of life. Children, with their dirty hands and noisy behaviors, were specifically prohibited from using these early public libraries.

The situation began to change after the publication in 1876 of a study of the “history, condition, and management” of public libraries by the U.S. Bureau of Education. One of the contributors to that study, William I. Fletcher, argued that public libraries should change their policies limiting access to children. He based his argument on the need to develop a taste for refined reading early in life, writing,

If there is any truth in the idea that the public library is not merely a storehouse for the supply of the wants of the reading public, but also and especially an educational institution which shall create wants where they do not exist, then the library ought to bring its influence to bear on the young as early as possible.^[1]

Fletcher's message was consistent with other ideas beginning to circulate at that time about the need to reach children early in their lives in order to influence the kind of adults they would become. John Dewey's ideas about education and G. Stanley Hall's theories of child psychology began to influence other fields. The new specialists in library services to children, the first children's librarians, were convinced that young people who were exposed to the best in fine, uplifting literature would grow up to become fine, uplifted adults. Betsy Hearne and Christine Jenkins describe their approach as a kind of visionary quest in which the “grail was not just information or even knowledge but the enrichment of experience through whole reading, the kind of reading that engulfs the heart as well as engaging the head and ultimately shapes a lifetime.”^[2]

By the end of the nineteenth century, libraries across the country had begun to open their doors to children. Administrators began to recognize the need for specialist staff—children's librarians—who would provide services for this new clientele. Some remarkable women answered the call and defined those services with such passion and

force that they left an indelible imprint that has lasted for more than 100 years.

Among the pioneering children's librarians were Frances Jenkins Olcott, the first head of the children's department of the Carnegie Library of Pittsburgh, Caroline Hewins at the Hartford Public Library, and Anne Carroll Moore, supervisor of children's services at the New York Public Library from 1906 until 1941. Moore deserves special mention for her role in defining and institutionalizing public library services for children.

Anne Carroll Moore believed that the library should be an inviting and gracious environment for children. To this end, she created children's rooms that were warm and welcoming with books displayed on low, open shelving. She established circulation policies that did not discriminate against young library patrons. She provided rigorous training for the young women who worked under her supervision. She searched out the best books for children at a time when few existed except for a few nineteenth century classics and then encouraged publishers to establish separate children's divisions. She encouraged authors and illustrators to create new books for children, and then she reviewed those books for some of the most influential publications of the day. Her opinions were never tepid, and not everyone in the children's literature community appreciated her hegemony over the field. However, her contributions to the early development of children's librarianship are unrivaled.^[3]

The pioneering children's librarians took their message about the importance of libraries in forming children's reading interests to the annual meetings of the American Library Association (ALA). Their voices were heard; and by the end of the 1920s, even the smallest public libraries stocked books for children and provided some of the services that were becoming standard, such as summer reading and storytelling programs. Andrew Carnegie did his part by including designated space for children in his massive public library building program.^[4] The events of the Great Depression of the 1930s and World War II put further development of children's services on hold. However, the post-War years proved to be boom times for American families and for public library services to children.

Many innovations in those services were institutionalized during the last half century. An explosion in children's book publishing led to a new focus on evaluating books, systematically developing collections, and promoting the books with children through techniques such as booktalking and merchandising. Preschool story hours introduced 3- and 4-year-olds to the experience of listening to stories in a group. A new awareness of poverty and racial inequities in the 1960s led to outreach efforts and nontraditional programming designed to appeal to populations who had not been library users in the past.

Taxpayer revolts in the 1980s resulted in a movement for accountability in local government operations;

children's librarians responded with the development of output measures.^[5] The rise of the Internet generated apocalyptic talk about the death of the library; children's librarians responded with programs to teach children and their families how to use information and communication technology more effectively. There was national concern about children's poor reading skills; children's librarians responded with a research-based program designed to educate parents in techniques to prepare their young children to learn to read.^[6]

Today's library, in response to concerns about preparing children for the future, has expanded services to support learning in science, technology, engineering, art, and math. Many libraries are incorporating Makerspaces, where a variety of tools (anything from sewing machines to 3D printers) are available for children and families to learn, share knowledge, and make things. Libraries are also sites for community gardens and summer lunch programs. In fact, the majority of programs in public libraries are geared for youth and the demand for these programs continues to grow.^[7]

A Pew Internet study states that "70% of parents report their child visited a public library in the last 12 months and 55% say their child has his/her own library card."^[8] The report also points out that adults who have children or grandchildren are more likely than other adults to use the library themselves. A vast majority of parents hold the opinion that access to the library is important for their children. The remainder of this entry will examine how children's services in libraries are organized and will explore current issues in the field. Finally, it will look briefly at children's services at international libraries.

CONTEMPORARY LIBRARY SERVICES TO CHILDREN

Implementing Children's Services within the Public Library

Library service to children has evolved into a distinct specialization within the profession. In most public libraries, these services are provided through a designated department or division. In large libraries, these departments are ordinarily headed by a manager or coordinator of children's services who provides training and general oversight for service to children. In smaller libraries, an individual children's librarian may be responsible for the work.

A few public library systems have moved away from specialist designations for children's and adult reference librarians in favor of a more generalist approach. In these situations, all public service librarians are presumed to be able to serve the needs of children, as well as teenagers and adults. A children's services coordinator or manager

may be on staff to organize programming and train all staff in some of the skills needed to serve children well.

Service to children is almost always provided in a special space within the library. Lower shelving and child-sized furniture are the basic elements in a separate children's room or the children's wing in a library with an open floor plan. However, most of these open floor plans use other features such as color, wall decorations, toys, games, fish tanks, and puppet stages as indicators that this part of the library is meant for young patrons. Computers have become a standard feature in children's areas everywhere. Some are especially designed for the youngest patrons, loaded with educational software and games.

Two recent trends in library spaces for children are worth mentioning. One is the creation of "destination" sites, designed as exciting discovery centers for children.

These libraries use elaborate decorative elements and interactive installations to lure children and families to spend time there. One of the most striking of these new approaches is the *ImaginOn*, a collaborative venture of the Charlotte–Mecklenburg Public Library and the Children's Theater of Charlotte in North Carolina (Fig. 1). Opened in 2005, this 102,000 ft² building is filled with dynamic modules intended to "bring stories to life through extraordinary experiences that challenge, inspire, and excite young minds."^[9] The Phoenix Public Library employed a designer with a background in children's museum work to create custom installations in its picture book areas. These installations encourage young children to develop small motor skills, phonemic awareness, and letter awareness in a developmentally appropriate and child-friendly environment.

The second significant trend in library facilities for children is the Family Place Movement.^[10] Family Place Libraries is a joint initiative of the Middle Country Public Library in New York and Libraries for the Future. It is

now a nationwide network that includes 435 librarians from 25 states. Family Place Libraries aim to help parents and caregivers become more intentional, informed, and active participants in their young children's development. A key component of their program is a specially designed space within the library where parents can gather with their young children to play, learn, and observe. These spaces have collections of toys, music, and parenting materials in addition to the usual books for preschool children.

Range of Services

The overarching goals of contemporary library services to children are to promote reading and literacy and to ensure that children have access to information in all formats. These goals are achieved through a wide range of services. Collection development is the foundation for most of those services.

With more than 5000 juvenile titles published in the United States each year, it becomes critical to select the most appropriate books for any particular library collection. Children's librarians in large library systems may have access to review copies that they can evaluate firsthand. Most, however, rely on reviews in sources such as *School Library Journal*, *Booklist*, *Kirkus Reviews*, and *The Horn Book*. They make their decisions based on budget, community needs, judgments about quality, and other standards, all codified in a collection development policy. Knowledge of the collection—and the broader field of children's literature—is a fundamental part of the children's librarian's toolkit.

After books are added to the collection, they are typically organized on the shelves according to format and genre. Picture books are housed in low shelving designed to accommodate large formats. Nonfiction and fiction

Fig. 1 Interior of the Spangler Library, *ImaginOn*, Charlotte, North Carolina.

are separated, and there may be special sections for easy-to-read primer, ABC and other concept books, folk and fairy tales, and parenting materials. CDs and videos (DVDs) are also standard materials in children's collections today.

Since reading promotion is the *raison d'être* for the book collection, children's librarians promote the books in a variety of ways. They create book displays and book lists to highlight segments of the collection. They work one-on-one with patrons in the library, providing expert readers' advisory and reference services. They promote specific books to groups such as school classes—an activity known as booktalking. They mount summer reading programs designed to motivate children to read during the months when they are not in school.

Storytelling is another basic service provided in almost all public libraries. Originally, as conceived by Anne Carroll Moore at the New York Public Library in the early 1900s, this was exclusively the telling of traditional folktales to audience of school-aged boys and girls. While some librarians still practice the traditional art of storytelling, it is much less common than story hours for preschool children.

The preschool story hour was popularized in the years after World War II when the baby boom was impacting communities—and libraries—in all parts of the country. As originally conceived, it catered to 3- and 4-year-olds who were developmentally ready to participate in a brief group experience away from their parents and caregivers. In a period of about half an hour, the children's librarians would present a variety of picture books, flannel board stories, finger plays, and nursery rhymes or songs. While the traditional preschool story hour is still a staple in many public libraries, it has evolved into a broad menu of programs for young children—lapsit programs for infants, toddler storytimes for 2-year-olds, and family storytimes designed for the broadest possible age range. Increasingly, the use of technology is being incorporated into storytimes and it is now considered good practice to include parents and caregivers in library programs for young children. In fact, parent education is now an integral part of much early childhood programming in libraries.

In addition to programs in which librarians and other storytellers read or tell stories to children, there are also planned ongoing programs in which children are encouraged to read aloud, a practice that helps to develop reading fluency. Grandparents and Books is one such program. Older adults are trained in techniques for engaging children in literacy and literacy-oriented activities, including having the children read to them. The grandparents then volunteer to be available to the children after school in the library reading rooms.^[11] Literacy dogs are another recent innovation in library programming. Children are invited to read aloud to specially trained dogs. Reluctant or less fluent readers apparently find the patient animals to be perfect listeners. There are programs using specially trained therapy dogs as reading partners for children at

many public libraries. One good example is R.E.A.D. (Reading Education Assistance Dogs) at the Salt Lake City Public Library.^[12]

Besides storytelling, children's librarians typically provide other kinds of programming: puppet and magic shows, visits from Seeing Eye dogs and snake handlers, cooking and sign language classes, and much, much more. Makerspaces are becoming commonplace in libraries. Makerspaces provide space and tools for creativity, knowledge sharing, and collaboration. While they are often thought of as providing access to technology such as 3D printers, special software, and electronic devices, in fact they can provide a wide variety of learning and creative opportunities. Makerspaces can be a place to learn to fix a bicycle, knit, solder, code, or otherwise make things depending on the needs and interests of the community.

Community gardens are another increasingly popular library program. Community gardens serve a variety of educational and recreational needs and are being used in libraries with children of all ages. In addition to teaching gardening skills, they foster nutritional and environment literacies, and teach plant identification. The garden experience connects quite naturally to books and other information sources provided by the library.

Another recent innovation is summer meal programs in public libraries. Often partnering with the U.S. Department of Agriculture, these programs help to ensure that young people in low-income areas have access to healthy food during summer vacation from school. Summer meal programs introduce the library to often underserved populations to the resources the library offers, build community partnership, and provide opportunities for positive youth development.^[13]

Many of the programs provided by the public library are not held in the building itself but are taken out into the community into a variety of venues from schools to recreation centers to parks and playgrounds. This kind of outreach is intended to extend the library's sphere of influence, to enhance the library's visibility, and to make services available to children who might not be able to physically get to the library itself. Children's librarians also work to develop strategic partnerships with other child-serving leaders and organizations in their community. Almost all children's librarians maintain some kind of relationship with the schools in their communities. They may invite school classes to visit the library or go into classrooms themselves to promote library services and reading.

In spite of this emphasis on programming, the heart of library service to children is still one-on-one readers' advisory and reference work. Children's librarians bring their specialized knowledge of their collection together with their understanding of children to advise young people as well as their parents, caregivers, and teachers about books to read for pleasure, information, and enlightenment. Queries range for a mother's request for a book to help

her 3-year-old adjust to the death of a grandparent to a 12-year-old's pleas for a book as good as the last Harry Potter to a fifth-grade teacher's need for good fiction titles to supplement the American History curriculum.

Reference services for children are often related to homework needs. While school libraries are the best first resource for homework, their hours are often limited. Furthermore, not all schools provide adequate libraries. The public library fills the gap. Many public libraries allocate special resources to provide homework help during after-school hours.^[14] These can be as modest as a special shelf of homework-oriented reference books or as elaborate as well-equipped Homework Centers staffed with aides or tutors especially trained to assist young people with their homework needs. These homework services are particularly appreciated by families in which parents are not fluent in English or familiar with the American school system and by working parents who have limited time to spend with their kids on school nights. Homeschool families also make extensive use of public library facilities.

As electronic resources have become increasingly useful resources for children's homework needs, librarians have also begun offering instruction in the information literacy skills needed to navigate the Internet effectively. They may offer this instruction informally, as part of their reference interview, or more formally through classes and workshops.^[15]

Children's Librarians

In 1905, in a report to the ALA, Frances Jenkins Olcott described the ideal applicant to the newly established training school for children's librarians at the Carnegie Library of Pittsburgh:

Sympathy with and respect for children, strength of character, a genial nature, a pleasing personality, an instinct for reading character, adaptability, and last but not least, a strong sense of humor. Her home training and education should have given her a love and knowledge of books, a fund of general information, a quick and accurate mind. These qualities are difficult to find combined in one person.^[16]

It is no longer assumed that the ideal children's librarian is female, but many of the desirable characteristics described more than 100 years ago are relevant today, and they are still difficult to find combined in one person. However, perhaps in keeping with newer thinking in human resources management, we tend to think today in terms of competencies rather than personal traits. The Association for Library Service to Children (ALSC) has developed and maintained a comprehensive outline of the competencies that children's librarians are expected to demonstrate on the job. The most recent edition of this document was released in 2015.^[17] The competencies are

grouped into seven broad categories: commitment to client group; reference and user services; programming skills; knowledge, curation, and management of materials; outreach and advocacy; administrative and management skills; and professionalism and professional development.

Outstanding Library Services to Children, a publication sponsored by ALSC, provides useful guidance for achieving and maintaining those competencies. The author makes clear that nobody is expected to have mastered all of the competencies before starting his or her first job and that most children's librarians will be more proficient in some areas than others. They acknowledge the extremely broad range of knowledge and skills required to do the job well, calling children's librarians, "the original multitaskers of the library world."^[18]

A master's degree from an ALA-accredited graduate school is the standard educational requirement for children's librarians. In addition to the core curriculum that prepares all professional librarians, they typically take courses related to children's literature, collection development, and children's programming. In many master's degree programs, there is an emphasis on customer service, understanding the user group, and management. The integration of technology into LIS education has furthered the inclusion of technology tools into course content including a variety of media and applications.^[19]

The Laura Bush 21st Century Librarian Program of the federal Institute of Museum and Library Services (IMLS) has provided resources to help libraries and graduate schools of library science fund the development of new information professionals, including youth librarians. Grants have provided scholarship funds for both master's and doctoral students, helping to meet the need for children's librarians and faculty to teach them.

Children's librarians are supported in their efforts to serve children and in their own professional development by various professional associations. The primary national organization is the ALSC, a division of the ALA. State library associations usually have a division or section devoted to children's services as well and often provide an entry point for professional involvement by novice children's librarians. Some children's librarians also participate in related professional associations such as the International Literacy Association or the National Association of the Education of Young Children.

Issues

IT is significant that library service to children has continued to evolve over more than 100 years since it began. Some of the core values and service that were identified by the early leaders in the field remain at the heart of the specialization today. However, society has undergone major changes in the last century, and the rate of change continues to increase. Children's librarians are struggling to redefine and reinvent the services they offer in a

turbulent environment. This section will outline some of the issues that are currently driving calls for innovation in the field—specifically, changing notions of childhood; the increasing cultural, ethnic, and racial diversity of the populations served by public libraries; technological imperatives; and the demand for demonstrable outcomes of services.

The founding mothers of library services to children had few doubts about the clientele they served. Their patrons were school-age children. While some of the great early illustrators such as Randolph Caldecott and Kate Greenaway had produced picture books for young children, there was not yet a well-defined preschool market for publishing or for public library services. Adolescence had yet to be identified as a distinct developmental stage, and childhood for middle- and upper-class children extended at least into the early teens. Working-class children were usually expected to take on adult responsibilities by the age of 13 or 14.

As many historians and sociologists of childhood have demonstrated, however, childhood is a malleable social construct.^[20] By the beginning of the twenty-first century, American childhood had contracted. Adolescence was occurring both physically and socially at an earlier age, and children as young as 8, 9, and 10—“tweens”—were taking on the characteristics of teens in training.^[21] At the same time, discoveries in cognitive science made it clear that the earlier years of human life, from birth to age four, are enormously important developmentally. Many children's librarians have responded to this shift in our understanding of the span of childhood by shifting their priorities away from the older middle school child in favor of working with parents and caregivers of very young children. The ALSC continues to define its clientele as children from birth to age 14, while the Young Adult Library Services Association, a sister division of ALA, claims the age group from 12 to 18. Public libraries are not consistent in their classification of service population by age, and presumably, young people between the ages of 12 and 14 will gravitate to the area of the library in which they fell most comfortable.

Whatever their age, twenty-first-century children live in a world that would be almost unrecognizable to Anne Carroll Moore and her peers. Two dramatic changes in American society have a particular impact on children and on the services provided for them by public libraries. One is the ever-increasing racial and ethnic diversity in our country as well as changing attitudes toward this diversity. The other is the impact of new and emerging communications and information technologies.

The changing ethnic and racial composition of the United States has been well documented. In 2014, only 52% of children in the United States were non-Hispanic White. Non-Hispanic Black children were 14% of the population; Asians, 5%; and Hispanic, 24%. Immigration

patterns and differential birth rates do much to explain the shifts, and some states—such as California—show more dramatic changes. There, the 2014 statistics show that only 26% of the children were non-Hispanic White. Non-Hispanic Black children were 5% of the population. About 52% of California children are Hispanic; 11% are Asian.^[22] Understandably, library patrons are also increasingly diverse.

The increasing diversity of the children using public libraries impacts both collections and the services provided for them. Many communities now find it appropriate to stock books, videos, and recordings in languages other than English. The International Children's Digital Library has filled a gap for some libraries by seeking out and digitizing books in languages that are more difficult to find in the United States, such as Farsi, Croatian, or Maori.^[23] Collections of children's books in languages other than English are particularly important resources in immigrant communities. These collections enable parents to share books with their children in their mother tongue and often serve as tangible evidence that the public library is a welcoming and relevant institution in their adopted country.

The increasing diversity of library patrons has highlighted some staffing and recruitment needs. Bilingual librarians are in great demand, as are those from diverse racial and ethnic backgrounds. Unfortunately, the library profession has traditionally attracted White females. Demographic statistics for the total library workforce are somewhat elusive, but ALA estimates that about 73% of credentialed librarians in 2010 were White.^[24] There have been numerous efforts to recruit more diverse students to library school through such efforts as the ALA Spectrum Scholarships. For the academic year 2013–2014, approximately 67% of students graduating from ALA-approved master's degree programs were White and approximately 77% were female.^[25]

The rapid proliferation of digital information and communication technologies has generated other kinds of challenges for the traditionally book-oriented field of children's librarianship. The children being served in public libraries today have grown up with computers and the Internet. IT has affected the way they learn and play. However, disparities caused by income gaps have created what has become known as the digital divide. Discussion about the digital divide includes concerns about access to computers as well as access to broadband (continuous high-speed connection to the Internet). The Children's Partnership reports that

Compared to their peers in households with annual incomes over \$75,000, children in households with annual incomes less than \$15,000 are

- 1/2 as likely to have a computer at home
- 1/3 as likely to have the Internet at home
- 1/7 as likely to have broadband at home^[26]

Public libraries have responded aggressively to help bridge the digital divide. Public access to the computers and to the Internet is now a standard service in libraries across the country. Because of the provisions of the Children's Internet Protection Act, many libraries have installed filtering software on computers in their children's areas.^[27] This restriction has been a source of conflict for many children's librarians who are torn between their advocacy for children's intellectual freedom rights and their desire to protect children from exposure to pornography and other harmful matters.

It is not unusual to see three or four children crowded around each computer in the children's area while the book stacks stand as empty as ghost towns. Many librarians applaud this development, citing in particular the welcome sight of boys returning to the library. Some are concerned, however, that children seem to be using the Internet primarily to access games sites rather than for informational purposes. In any case, the seamless integration of computers into the service plan and general operation of library service to children has not yet been fully accomplished. Computers still feel like add-ons in many children's libraries (Fig. 2).

There are some promising developments, however. Libraries that offer after-school homework assistance have found that computers are a natural learning tool. Some libraries have made an effort to offer tutorials in information literacy skills to parents and children. Many libraries are integrating games of all types into library programming.

The third issue of interest in contemporary library service to children is the pressure to document demonstrable outcomes. Funding sources ranging from granting agencies to local governments are asking for evidence that the services libraries provide make a difference in the lives of children and families. No longer satisfied with simple

output measures such as circulation and reference counts that tell "how many" or "how much," they now want answers to the question, "so what?" The kind of research necessary for conducting good outcomes evaluation studies is rigorous and often expensive. Eliza Dresang, Melissa Gross, and Leslie Edmonds Holt have produced a good how-to-do-it manual based on their own IMLS-funded work at the St. Louis Public Library, but doing this work still requires more commitment and expertise than most public libraries can command.^[28] Some library systems have contacted with academic partners to do outcomes evaluation of specific grant-funded projects, but the resulting studies have not been generalizable to other libraries.

INTERNATIONAL DIMENSIONS

Service to children has tended to be included as an element of public library services in countries around the world. In most respects, this service has followed the American model with an emphasis on books and reading. The Standing Committee on Libraries for Children and Young Adults of the International Federation of Library Associations and Institutions (IFLA) has published guidelines for children's services that advocate the kind of outreach, networking, collection development, and programming that are institutionalized in most American libraries. The IFLA document cites the United Nations' "Convention on the rights of the Child" as an underlying statement of principles that should guide library services.^[29]

Of course, countries vary in their funding base, opportunities for professional education, and local community values and practices. Scandinavian libraries, for example, have a tradition of partnering with local cultural

Fig. 2 Computer stations in the children's room of the Central Library, Minneapolis, Minnesota.

institutions and of furthering what they call “children’s culture,” including such manifestations as children’s theater and musical performances. In some cases, they have also pioneered effective technological innovations. The Interactive Children’s Library of the Aarhus Public Libraries in Denmark is designed especially to attract children through applications of digital technology. The Children’s Community Libraries in Singapore are also known for their integration of technology with book collection in English, Chinese, Malay, and Tamil in well-designed modern facilities. The children’s library of the Bibliotheca Alexandrina on the site of the original ancient Library of Alexandria in Egypt, limited to children over the age of seven, is a beautiful section in the iconic new building offering many of the services we have come to expect in a contemporary public library. Interestingly, children are not permitted in the adult department of the library there. Websites for each of the libraries mentioned include some information in English. Public libraries in Croatia have responded to the lack of early childhood education offerings in their country by creating special playrooms for children from birth through six, the age at which they are able to enroll in school. Many libraries employ people with dual degrees in library science and early childhood education to provide formal programming in the playrooms (Fig. 3).

In some developing countries, library services to children are provided as often through nonprofit organizations and volunteer initiatives as through government-funded public libraries. An interesting example is the Banco del Libro in Caracas, Venezuela. This volunteer effort begun by a group of women more than 49 years ago was instrumental in developing the first library network and the first bookmobile service in that country. The Banco del Libro went on to form a children’s literature examination center, the first children’s book publisher, and the first specialized children’s bookstore in Venezuela.^[30]

Public libraries in African countries struggle to find funding for services to children. They are also hampered by the lack of material in local languages since there is little or no publishing or trade of children’s books in sub-Saharan Africa. Almost all efforts to put books into the hands of children are supported by international nongovernmental organizations such as the British Book Aid or the Canadian CODE. These groups work with local individuals and institutions to produce children’s books in local languages. The results are often didactic and fall well below the quality standards of Western publishing houses, but they do meet some important local needs.

Another interesting example is the Lubuto Project that is currently operating in Zambia. The Lubuto libraries began as an individual voluntary initiative on the part of one American librarian living in Lusaka. She began by volunteering to read to street children made homeless by the loss of parents to AIDS at Fountain of Hope, an agency providing services for that overwhelmingly needy population. This led to a temporary library housed in an abandoned shipping container. The project celebrated its 10th anniversary in 2015 and has received grant funds to build their fifth library.^[31]

CONCLUSION

Library service to children has evolved from the first specialization within library services in the United States to a well-institutionalized practice. Its proponents have redefined its mission and extended its parameters while retaining the original values exemplified by the motto, “the right book for the right child.” Some aspects of the service—summer reading programs, preschool story hours, and individualized reading guidance—are near universal elements of public library service. Emerging

Fig. 3 Playroom, Medvescak Public Library, Zagreb, Croatia.

services such as promotion of early childhood literacy through education of parents and caregivers, after-school homework assistance, and the provision of Internet access have achieved wide acceptance in the field. Children's librarians network actively and form partnerships with other community organizations in their efforts to advocate for children more generally.

Abstract

This entry examines the challenges and the path of library development in China, with emphasis being given to the twentieth century when new library institutions and practices were first introduced. In just over 100 years Chinese libraries and librarianship have evolved from ancient royal depositories to modern information centers. This entry discusses the underlying political and social changes and examines the contributions of important leaders who have promoted China's library development. An overview of some of the important archives and repositories in the country is presented.

INTRODUCTION

The largest of all of the Asian countries, China (Zhongguo) occupies nearly the entire East Asian land area. It extends for about 3,100 miles (5,000 km) from east to west and 3,400 from north to south, covering an area of about 3,696,100 square miles (9,572,900 square km). In size China is almost as large as the entire continent of Europe. China's land frontier is approximately 12,400 miles in length and its coastline is about 8,700 miles. The country is bounded by Mongolia to the north; Russia and North Korea to the northeast; the Yellow Sea and the East China Sea to the east; the South China Sea to the southeast; Vietnam, Laos, Myanmar (Burma), India, Bhutan, and Nepal to the south; Pakistan to the southwest; and Afghanistan, Tajikistan, Kyrgyzstan, and Kazakhstan to the west. China also faces South Korea and Japan, across the Yellow Sea, and the Philippines, beyond the South China Sea (see Fig. 1, Map).

China has the largest population of any country in the world, 1,330,044,544 (July 2008 est.). Similar to other large countries, China is multiethnic. The Han people comprise 91.5% of the majority group in China, while the remaining minorities the Zhuang, Manchu, Hui, Miao, Uyghur, Tujia, Yi, Mongol, Tibetan, Buyi, Dong, Yao, Korean, and other nationalities comprise 8.5%. The Han group speaks Chinese and most of the minorities speak other languages.^[1]

History

Until the mid-nineteenth century, China was the dominant power in East Asia. Chinese Confucian teachings, along with institutions and practices, were introduced into Japan,

Korea, and Vietnam. The Chinese system of education, based upon the Chinese classics, was reverently followed and mastered by scholars in these countries.

In China the earliest known documents were those carved on tortoise shells and animal bones. The collection and preservation of such documents can be traced back to as early as the Shang Dynasty (1600–1100 B.C.) when royal archives or libraries were first maintained. China had an imperial library in each dynasty throughout her long history, from the Shang to the Qing (1644–1911 A.D.) dynasties. The imperial libraries served as depositories of national literature and archival documents and were for the use of the imperial family, high officials, and noted scholars. These libraries were not opened to the public. The keeper of the library was little more than protector of this private collection; there was no known formal training for librarianship.

China's traditional libraries experienced remarkable development during the Tang Dynasty (618–906 A.D.) and Song Dynasty (960–1279 A.D.) when block printing became popular and movable type printing was invented. During this time there was a much wider diffusion of printed materials and both official and private collections blossomed. From the tenth century onward, printed versions of the classics and other writings were more readily available, and the door was opened for education for greater numbers—especially those training for governmental service. China's libraries were then composed of royal collections, academic and private collections, and cloister or temple collections. Access to these volumes was mainly restricted to nobles and scholars.

Not until the nineteenth century was the importance of libraries recognized in the context of developing a modern educational system for China. Following the defeat of China in the Sino-Japanese War of 1894–1895, political

leaders and intellectuals realized the need to modernize and improve the educational system in order for China to prosper and be strong. The Reform Movement of 1898 was launched and part of the proposed reform plank was educational reform following Western practices. Among the Chinese intellectuals advocating a new model of librarianship was Wang Kang Nian. In 1896, he wrote that

The key to revitalize China lies in education. Education depends on the ability to master new knowledge and the mastering of new knowledge can only be accomplished through the establishment of schools, study, societies, and libraries. . . Every Western library collects tens of thousands of books in all languages and herein lays the key to a prosperous China.^[2]

Libraries were now linked directly to China's education and overall development.

The founding of the Republic in 1912 brought an end to the institutions and practices of the imperial system, and China began the difficult and long process of economic, intellectual, and political change. New knowledge was diffused to the population and the use of a Chinese phonetic alphabet was introduced. Following the May 4 Movement in 1919, books and periodicals in the colloquial language were published. Soon translated works of Peter Kropotkin and other foreign writers were in high demand among Chinese intellectuals. Libraries to meet the demands and needs of the new era were now faced with changing conditions and new challenges.

Beginning in the 1920s, four main types of Chinese libraries developed: public libraries, college libraries,

society libraries, and special libraries. Of the four, college or academic libraries held the best collections of Chinese and foreign books. These new academic libraries began to use the latest organizational and cataloging systems; their library facilities and equipment were also of higher quality than those of the public libraries.

The Republican period on mainland China (1912–1949) witnessed the beginnings of the introduction of modern librarianship, albeit repeatedly curtailed by civil and international conflicts. Beginning with the founding of the People's Republic of China (PRC) in 1949, and especially following the initiation of the “opening and reform” policy in the early 1980s, library development greatly accelerated.

Modern Librarianship in China

By the mid-nineteenth century, Chinese sovereignty was severely compromised as a result of the “unequal treaties” following China's defeat by Britain in the first Opium War (1839–1842). The economic, cultural, and political penetration and exploitation of China by the Western and Japanese powers and the decline of the Qing (Manchu) Dynasty (1644–1911) over the next half-century contributed to the instability of the nation. Although the Manchu governing class had introduced some reforms at the end of the nineteenth century, popular uprisings from the mid century on—from the Taiping Rebellion (1850–1864) to the Boxer Rebellion (1900)—demonstrated that all was not well. The traditional Confucian order of guarding

against any contact between the Chinese and foreigners (who were regarded as barbarians) eventually gave way to trade with the West, missionary endeavors, introduction of Western technologies and political institutions. The influx of foreign educators and the enrollment of Chinese students in Western colleges provided external political and cultural stimuli for change. As a result of the Western and Japanese intrusions in Chinese affairs beginning in the 1840s, many traditional Chinese institutions were shaken, including the closed-access model of Chinese libraries carried over from ancient times.

The beginnings of modern Chinese librarianship can be traced to the Public Library Movement (1840–1926), with its interest in following developments in European, American, and Japanese library systems. Many Chinese intellectuals recognized that it was essential to modernize and improve education for China to prosper and be strong, and some of these reformers recognized the potential role of libraries. Liang Qi-Chao, scholar, literary journalist, and political figure, emphasized the importance of establishing libraries to spread culture and train talented people; he introduced into China the term library, “tushuguan,” from Japan.^[3] This new term appeared for the first time in 1896 in *Current Affairs Newspaper*, which Liang Qi-Chao edited. Later Liang traveled to the United States and visited public, university, and national libraries in Boston, New York, and Washington, District of Columbia in the early twentieth century. He quickly discerned that public libraries were necessary for public education. What impressed him most was the open-shelf arrangement of American college libraries. He also became convinced that libraries were linked directly to America’s educational and economic development.

The Public Library Movement (*Gong Gong Tushuguan Yundong*)

The Public Library Movement marked an end of Chinese feudal society and the beginnings of great changes and reform, socially and politically. European, American, and Japanese library systems played a predominant role during this period.

During 1917–1926, the Chinese public library movement was at its height. Two primary factors contributed to this: 1) the Literary Revolution and Renaissance Movement, which occurred during 1917 when “pei hua” or the colloquial language was introduced as a medium of literary expression; and 2) the May 4th Movement of 1919 which unleashed the New Culture Movement in China by challenging aspects of traditional culture that dominated the lives of the Chinese for more than 2000 years. Confucianism was repudiated, setting the stage for dramatic cultural changes.^[4]

Influenced by the West, the Mass Education Movement of 1920 had the goal of teaching illiterates to read and write using 1000 characters. Such initiatives had

important implications for the development of public libraries. It should be noted that at this time the majority of public libraries were maintained by the educational budget of local districts and were under the control of the provincial commissioners of education. The majority of reading rooms had noncirculating materials. Imposition of a small fee even for in-house use of library materials was common in many public libraries, mainly to keep away vagrants. By the mid-1920s the traditional idea of charging fees for admission gradually was being discarded, but borrowing books for home use was not yet widely accepted. It was in the free public libraries that newly published works on various subjects were made available as well as copies of Chinese classics. Children’s reading rooms were also maintained in these libraries, though they were still in their infancy in China. Often preexisting buildings (such as old palaces, former academies, and abandoned temples) were turned over by the authorities to be used free of charge as libraries and reading rooms.

The Public Library Movement, 1840–1926, evolved into the Modern Library Movement (*Xin Tushuguan Yundong*), 1911—to the present, which not only advocated for more public libraries, but also promoted the development of college and university libraries, and special libraries. At this time special libraries were most prevalent in major cities such as Beijing, Shanghai, and Guangzhou (formerly known as Canton) and were founded mainly to provide information for government organizations and bureaus in China. The Modern Library Movement (also called the New Library Movement) sought to eradicate traditional library practices, promoted Western librarianship throughout China, introduced Western library science and technology, and raised the social standing of Chinese librarians.^[5]

Library Science

At the beginning of the Chinese Republic in 1912, many reformers realized the need to replace the traditional practices of Chinese library administration. Since many Chinese intellectuals were influenced to some extent by Japanese culture and science before the Revolution of 1911, Japanese library science was the first foreign model introduced into China. In 1910 Xie Yun-Cang translated *Library Education* which was authored by a Japanese scholar and published by Fengtian Press; this was the first book about library science published in China.^[6] After Shen Zhu Rong returned from the United States in 1917 (discussed in the “American Influences” entry) and launched the Modern Library Movement, the emphasis on foreign library science shifted from Japan to the United States. Between 1919 and 1949, many articles were translated into Chinese that dealt with “American Public Libraries” and “American Librarianship.” Even lectures on the Library of Congress (LC) Classification, Dewey

Decimal Classification (DDC), Brown Subject Classification, and Cutter's Expansive Classification were translated and published by Chinese librarians. Thus the concept of an American-type library administration prevailed and later spread throughout China.

Prior to 1900 there were no card catalogs in China, only book catalogs. After the introduction of both Japanese and Western library science, card catalogs became popular. The Library of the North China Branch of the Royal Asiatic Society had catalog cards with Dewey classification numbers. Cutter's author numbers and index entries were in usage as early as 1908. The Boone Library (founded by Mary Elizabeth Wood in 1910, in Wuchang, now a district of the city of Wuhan, Hubei province) and Beijing libraries began using card catalogs in 1918. After the 1920s the majority of Chinese libraries adopted the card catalog system. Beijing Library as early as 1936 began to print and issue cards for the use of all libraries in China.

Sun Yu Xiu was the first person to introduce the DDC system into China. Sun said, "It is the most important and popular classification among all the classifications in English."^[7] Introduction of the DDC precipitated major changes in the development of modern Chinese classification system. Soon it was found that DDC was not adequate for Chinese works; the Chinese Si Ku classification or fourfold scheme was eventually merged into the DDC system: the four Chinese schemes included the following categories of works:

1. The six classics, lexicography, philology.
2. Philosophy, military science, mathematics, and divination.
3. History, anecdotes, state documents, and miscellaneous writings.
4. Poetry, eulogies, and treaties.

Shen Zhu Rong and Hu Qing Sheng led the way to combine the class heading of both Si Ku and DDC. The Boone Library published Shen and Hu "Modified Dewey Decimal Classification" in 1927. This had a great impact on all of the succeeding Chinese classifications. At the time, DDC was classified into the following 10 categories: General Works, Philosophy, Religion, Sociology, Philology, Natural Science, Useful Arts, Fine Arts, Literature, History and its many subdivisions, together with the fourfold Chinese classification. This led to several changes in the development of modern Chinese classification: 1) supplemented DDC to suit the headings for Chinese libraries; 2) mixed the class headings of both Si Ku and DDC; and 3) used DDC as a basis for class headings with additional new class headings according to the subject of the Chinese publications.

It can be seen that Anglo-American library science indeed had a strong impact influencing Chinese librarianship. But some technical functions could be adopted and others could not. For example, China could not completely

replicate America's classification system to their own library's system, since China had its own set of traditions and books that often could not coincide with those introduced from abroad. Therefore, modification and adaptation were the result of such encounters.

American influence

Let us examine the specific impact and role that America had on Chinese librarianship in modern times, exemplified by the work of Mary Elizabeth Wood and Arthur E. Bostwick. Mary Elizabeth Wood (1861–1931) came from a family of missionaries. She, herself, was later named a lay missionary of the American church. In 1899 Miss Wood visited her brother who was a missionary in Wuchang, China. At his suggestion Wood stayed on to take charge of an elementary English class in the small, missionary-run Boone College. While working as a teacher she became aware of the inadequate library facilities and collected donations (which she used along with her own funds) to open the independent Boone Library in Wuchang in 1910. The Library was opened to the public as well as students from Boone College. Here Miss Wood advocated the Western practice of open access to the stacks, which set a precedent in Chinese librarianship. In order to attract users to the library and to introduce American librarianship, Miss Wood conducted lectures in the Boone Library. Realizing that training of young professionals was essential to the development of Chinese librarianship, she financially assisted Shen Zhu Rong and Hu Qing Sheng to go to the United States and study library science. Miss Wood sowed the seeds for the rise of the Chinese Modern Library Movement by promoting professional training for Chinese librarians.

Shen Zhu Rong and Hu Qing Sheng, the two students who went abroad to study in 1914 and 1917, returned only to find that the knowledge they gained would be applicable primarily to foreign libraries and could not be completely adopted in Chinese libraries. Therefore, it became imperative that a Chinese institution of library education to train librarians be established. Shen Zhu Rong and Hu Qing Sheng worked with Miss Wood to found the Department of Library Science of Boone College in 1920. This was the first institute for modern library education in China. The institute, which became the Boone Library School was accredited as a college by the Ministry of Education in 1930, and became the premier institution for the training of librarians in China. The School was financially supported by American funding during 1920–1949; for example, American churches contributed \$8,000 annually and the American government returned each year \$13,500 of the Indemnities Fund of 1900 (Boxer Rebellion). It was through the determined efforts of Miss Wood that a campaign was launched to persuade the American government to return the indemnities of 1900 in order that the money could be used to

advance Chinese librarianship. Through two trips to the United States Miss Wood and her supporters succeeded in persuading the American government to return all the indemnities of 1900, allowing some of the funds for Chinese libraries.

In 1924 Miss Wood prevailed upon the American Library Association (ALA) to help her Chinese colleagues establish a national library association in China. She also invited Dr. Arthur E. Bostwick, Director of the St. Louis Public Library, to visit China and lecture on the philosophy and practices of American libraries. Dr. Bostwick arrived in Shanghai in 1925 and visited more than 50 libraries in China where he lectured and also presented films on American librarianship. He was so successful in advocating American library philosophy and practices such as open-access that many librarians in China wanted to emulate the American way of operating libraries. Bostwick's visit coincided with the founding of the Library Association of China (LAC) by the Beijing Library in 1925.

With the growth of the Modern Library Movement in the early 1920s, there was a growing need for coordination. The Chinese Association for the Advancement of Education (CAAE) (*Zhonghua Jiaoyu Chujinhui*) proposed in 1923 to establish local library associations. By 1924 a number of provincial and local library associations developed, with Beijing Library Association being the primary one. These local associations paved the way for the establishment of a national library association. In April 1925, the national LAC, *Zhongguo Tushuguan Xuehui*, was founded to welcome the visit of Dr. Arthur E. Bostwick. During its existence, the accomplishments of the LAC included providing services to academic and public libraries, publishing a series of reference works and two periodicals, and encouraging library cooperation on the national and international levels. In 1927, the LAC was one of the founders of the International Federation of Library Associations (IFLA). From its inception this association of Chinese librarians became the leading force in the Modern Library Movement or New Library Movement. Its aim was to encourage research in library science, to develop Chinese librarianship, and to strive for the cooperation of the libraries. Through the efforts of LAC the development of Chinese librarianship evolved from the promotion of American librarianship to the reformulation of Chinese librarianship.

The period 1925–1937 witnessed the beginning of Chinese national political consolidation and economic and social reconstruction. In the 1930s the national government at Nanjing under Chiang Kai-shek launched a program to make the library an indispensable agency in the construction of new China. Notwithstanding insufficient funds to further the movement, Chinese libraries continued to develop. According to a survey conducted by the LAC in 1935, there were 933 public libraries and 1002 popular libraries in China, as compared to 1922 when there were only 51 public libraries and 239 free

public libraries.^[8] Popular libraries were the result of the mass education movement beginning in the 1920s. They pushed these institutions to a new level and laid the foundation for further developments. Instead of just being a storehouse for the preservation of books, popular libraries began to serve the general public. Under the second Chinese library law (1915) on public libraries there were two sets of regulations: 1) regulations regarding governing popular libraries—these libraries were small, containing a few thousand books and a few reference books, including popular books, magazines, and current newspapers for everyone; and 2) regulations that libraries be established in all provinces and every administrative district—public libraries in this category would emphasize more the academic materials. These rules led to the growth and reorganization of public libraries.

Subsequent political events and discords had an adverse affect upon library development in China. For example, during the Sino-Japanese conflict of 1937–1945, the National Library of Peiping (*Guoli Peiping Tushuguan*) received very few books from foreign countries. During the years when much of Eastern China fell under Japanese occupation, limited foreign materials were collected in the cities of Chongqing and Kunming. After 1941 when the Japanese occupied major coastal ports, the importation of books and periodicals from abroad became scarce.

The founding of the People's Republic of China (PRC) and the Cold War

When the PRC was founded in 1949 the new government faced many challenges. China was in a state of chaos, economically, politically, and socially. Much of the country's industry, educational facilities, and social base were destroyed during the years of Japanese aggression (1937–1945) and during the civil war in China (1947–1949). The new government immediately set up plans for national, social, and economic reconstruction. Libraries and library service were to play a critical role in the reconstruction of China during this period. To assist in national development, China adopted Russia's experiences, theories, and principles for the construction of a socialist model of library service. The goals of the library were to be aligned with the following principle:

The main tasks of the People's Government in its cultural and educational work are to elevate the cultural standard of the people, train personnel for national construction, eradicate all feudalist comprador-type and Fascist thinking, and foster thoughts of service.

Thus libraries were to serve as providers of ideological doctrine and work related information.

With the establishment of the new government under Mao Zedong, China turned toward the Soviet Union and

Eastern European countries for assistance in building a productive socialist state. During this time many non-Eastern bloc countries, including the United States, adopted an embargo against China. Meanwhile the National Library's acquisition of Western materials diminished greatly and its mission was realigned, following Soviet library principles which were "to serve politics, production, workers, peasants, soldiers, and scientific studies."

As early as June 1949, Mao Zedong declared,

All Chinese without exception must lean either to the side of imperialism or to the side of socialism. Sitting on the fence will not do. Internationally, we belong to the side of the anti-imperialist front headed by the Soviet Union, and so we can turn only to this side for genuine and friendly help, not to the side of the imperialist front.^[9]

This principle was implemented on February 14, 1950 with the Treaty of Friendship, Alliance, and Mutual Aid between the People's Republic of China and the USSR. Mao's "lean to one side" policy reinforced the importance of Soviet influences on librarianship in China. As the national economy was gradually restored, the Ministry of Culture took steps to restructure the libraries, and promulgated a new slogan of "serving the readers by every means." All types of libraries, especially public libraries, promoted book circulation by providing recommended book lists to readers and book exhibits.

Libraries were replenished with new revolutionary publications which were placed alongside the classical works of Marx, Engels, Lenin, Stalin, and Mao Zedong. The government also banned books that opposed the policies and ideology of the Chinese Communist Party, including works that referred to capitalism (particularly to American life), feudalism, idealism, imperialism, and individualism. Throughout the country, libraries were required to inventory their historical works and to identify and remove all "reactionary" publications, including "Fascist," pornographic, and factitious types of literature. Collection development was closely tied to the various political objectives; when a policy was declared, books, relating to the policy were purchased and those with opposing viewpoints were banned.

During the early 1950s libraries developed rapidly throughout China. Chinese officials were interested in establishing an effective library system and sought to learn the operations and practices of librarianship from the Soviet Union. At this time many works on library sciences written by Soviet specialists and librarians were translated into Chinese. These works were collected in 1957 and published as *Translations on Library Science*. The Chinese also adopted many of the technical aspects of Soviet librarianship; for example, the new classification scheme was based on the four main classes of the 1955 Soviet Classification Model: 1) Marxism-Leninism; 2) social sciences; 3) natural sciences; and 4) generalia.

During the 1950s, examples of the most successful newly created libraries were the rural and labor libraries. The slogan, "Culture going to the mountains and the countryside," was used everywhere to foster Marxist education and the popularization of socialist culture. The Government threw open the library doors to readers; no longer was there admission charged, unlike the republican period when users were charged a fee. Under the new government, the masses were the ruling class and libraries were organized to serve the workers and peasants.

During the First Five-Year Plan, 1953–1957, there was a great push for the rapid development of the national economy. This was the time of the 1956 "March toward the Sciences" movement. There was a surge in the rural areas to establish commune libraries. These commune libraries grew; they were administered by local Party committees and run by local people. The materials were acquired through municipal libraries or donations and carried directly to users at work sites. Realizing the importance of education and culture, a major literacy campaign was undertaken during the 1950s. Schools attached to reading rooms in communes and work places taught literacy skills. During these years there was seen also a surge in the growth of labor union libraries. By the end of 1956, it was reported rural reading rooms reached 182,960 and it was these reading rooms that enabled the laborers and peasants to study the current events and policies during the agricultural cooperation period, to elevate their ideological awareness and the standard of their scientific knowledge and production techniques. The libraries for the workers were established to help increase productivity by making more science materials available. After the 1960s there was progress in conducting research on users' needs and demands to further improve scientific scholarship.

Various government ministries held administrative control over libraries:

- The public library system, which included the national, provincial, municipal, county, and cultural center libraries were under the Ministry of Culture.
- College and university libraries were under the Ministry of Education.
- Elementary and secondary school libraries were under the Ministry of Education.
- Trade union libraries were under the Trade Union.
- Special libraries were under appropriate government agencies.

It should be noted that this administrative structure was also based upon the Soviet system.

Beginning in 1952, as a result of the Cold War, China secured few Western language materials, due to the strained relations between China and Western countries. It was difficult to find channels through which to purchase Western language books, except through third parties such

as India, because of the strict embargo act imposed upon China by the United States and many of its allies. By the latter half of 1953 the great majority of foreign books acquired in China were from the Soviet Union and East European countries; these works were acquired not only through purchase, but also through bilateral exchange agreements. Through 1957, Soviet materials relating to science and industry were translated in great quantities; these Chinese translations of Russian works amounted to 38% of the total number of publications issued in China.^[10] Other books and periodicals were acquired, by purchase, gift, or exchange, from the Soviet Union and distributed to libraries, where they contributed to the development of Russian language collections, including those in the National Library of China's (NLC) collection.

For China, the decade of the 1960s was one of domestic unrest and foreign conflicts. This was the period of waning relationship with the Soviet Union. In the early 1960s, the Soviet Union withdrew all scientific and technical assistance to China, including library development aid. The ability of China to purchase and/or acquire on exchange the necessary Soviet scientific publications was largely curtailed. In an attempt to rectify this problem, China looked toward Japan and Western Europe for materials in advanced science and technology. Meanwhile, China also began a movement toward self-reliance; the populace was discouraged from reading foreign literature, and access to new scientific and technological developments from abroad was restricted.

The Cultural Revolution and recovery

During the decade between 1966 and 1976 the leaders of the Cultural Revolution sought to eradicate old thoughts, old culture, old customs, and old habits of the bourgeois classes of China's past. Many libraries in China were closed and some destroyed. All educational and cultural activities came to a grinding halt. Meanwhile, the West continued to impose an embargo on relations with China. During this time the progress of modern librarianship was interrupted.

After the Cultural Revolution, beginning in the late 1970s, Chinese librarianship recovered and began to adapt many of the new Western ideas and practices of library science and technology. Libraries in China were rebuilt, transformed, modernized, and began to play a key role in national development. After the introduction of economic reforms and the opening up of China in the 1980s, Chinese libraries developed rapidly. Chinese students enrolled in American and other Western library schools, and some also attended special seminars for practicing Chinese librarians in China. Those seminars held in China included some sponsored by national and provincial library organizations. For example, the National Library had organized many seminars across the country to stimulate library development; the Institute of Scientific and Technological

Information of China (ISTIC) sent information specialists to lecture to library and information science students in universities and colleges; in 1978, a national conference was held in Nanjing for libraries with significant classical collections to discuss the 1982 preparation of the National Union Catalog of Ancient Classical Books project—this led to special training classes held in Sichuan province to coordinate the project.

By 1979 China reestablished interaction with the West, including diplomatic relations with the United States. To facilitate China's quest to gain access to Western knowledge, an agreement was signed between the United States and China in August 1979. The Implementing Accord for Cultural Exchanges between the governments of the United States and China provided for the LC to send a full set of U.S. government documents to China's National Library of Beijing (*Guoli Beijing Tushuguan*) beginning January 1, 1980. In return the National Library agreed to send in exchange to the LC a comparable number of Chinese publications. For the first year, LC sent 20,000 publications to Beijing and received only 800 publications from the National Library. A year later, in 1981, the National Library of Beijing raised its number to 13,000 publications. The issue of equivalent content was also raised by LC, for Chinese titles included a wide selection, from scientific treatises to children's books. In 1995 LC urgently requested only Chinese government publications. Since China owned and controlled the country's publication activities, everything it published was classified as a government publication.^[11] Other exchange agreements with foreign nations provided an avenue for further acquisition of much needed scientific and technical information.

LIBRARY AND INFORMATION SYSTEMS AND SERVICES

Legislation

As early as 1909, the first library law in China was enacted by the Ministry of Education. According to this law, the aim of the library was to preserve Chinese classics, to disseminate knowledge, to provide research facilities, and to collect materials for the free use of the public. No one was permitted to check books out of the library. There were two kinds of materials in the library—rare editions for safe keeping in the library and ordinary publications for general reading. The rare items included those editions published in the Sung and Yuan dynasties and permission to use them was required by the library authority. Books classified for general reading were government and private publications. Regarding foreign publications, the library was not allowed to obtain foreign books for fear it would contain ideas distasteful to the Emperor, known as "Son-of-Heaven." The library law of 1909 applied not only to the national library, but also to libraries at provincial

capitals and county and district libraries. The national library was called the Metropolitan Library. The second Chinese library law on public libraries, Regulations Governing Popular Libraries in 1915, elaborated and specified that public libraries should collect popular books for the general public. This became the turning point in Chinese library history, that is, libraries became more democratic and were expected to provide education for everyone; they not only served provincial and other administrative units, but also public and private schools.

Later in 1916, the Ministry of Education requested that all publishers deposit a copy of their publications in the Metropolitan Library. It also mandated that every library in the provinces, counties, and districts be encouraged to collect books and manuscripts pertaining to the history and culture of their respective locality. The official deposit law was revised in 1926 when it required that every publisher should submit four copies of each new publication to the provincial department of education. These publications were to be distributed to the Metropolitan Library, the National Bureau of Compilation and Translation, the provincial library, and the local county library. Through the years, many rules and regulations concerning libraries have been issued: for example, three of the most important were the National Book Coordination Act of 1957, relating to fostering library service in China; the *Summary Report of Library Work*, 1980, encouraging governments at all levels to develop libraries and expand their services as part of their national planning; and the *Report Pertaining to the Improvement and Enhancement of Library Work*, 1987, from the Ministry of Culture and other ministries, urging the coordination of libraries, reform of library management, and adoption of modern technology. Since 1987 there have been many sets of regulations for special libraries in the development of science and technology to advance economic progress. In 2008, the first standard for the construction of public libraries was issued by the Ministry of Culture. The Ministry and the Library Society of China (LSC) are striving to draft legislation on libraries for the People's Congress, China's highest legislative body. The regulations that have been approved through the years have served the administrative management and smooth operations of libraries well.

National Library of China (*Zhongguo Guojia Tushuguan*)

In 1929 the Chinese Ministry of Education recommended that the Beijing Library and the Metropolitan Library be amalgamated under one management to form a National Library. The two libraries were reorganized under the name of the National Library of Peiping (NLP). Although the National Library functioned mainly as a reference library, it was open to all classes of readers, and in 1929 loan services were offered to libraries and individuals.

At that time the NLP also expanded its services as a center of bibliographical information, both nationally and internationally, and it served as a National Information Center for China. The years 1929 to 1935 were one of growth and development in the foreign language collection. During this time 68,479 volumes of foreign language materials were acquired through purchase, gift, and exchange. A total of 39,113 volumes (representing 57% of the total acquisitions) of foreign language materials were purchased. Approximately 40% of the collection acquired was for natural and applied science materials. Political upheavals and crises had a definite impact upon China's library modernization. The affect of procuring foreign collections was an example. During the Sino-Japanese conflict of 1937–1945, the NLP received few books from foreign countries. Beijing came under Japanese occupation and the library transferred part of its resources to Chongqing and Kunming. At that time, the policy of the NLP was to maintain and manage the various reference collections in Beijing, while the Chongqing and Kunming offices were responsible for the continued collection of Chinese and foreign materials. In the early part of the war, foreign language materials could still be obtained through Hong Kong and then shipped inland. There was, however, the problem that the National Library had no permanent library facilities in Chongqing and Kunming and the two cities were subjected to Japanese bombardments, resulting in the transfer of a portion of the collection to the countryside and another portion to various universities. Later in the war, especially after 1941, with Japanese occupation of all the coastal areas, books and periodicals from abroad became scarcer and their acquisition was finally suspended. After the Japanese surrender in 1945, part of the library's collection at Chongqing and Kunming was shipped to Beijing, but the number of volumes was not large.

From 1945 until the early years following the establishment of the PRC in 1949, the NLP received a considerable number of Chinese and foreign materials which had been held by the Japanese supported puppet government of Wang Qingwei. This was especially true of Japanese language materials that numbered in the tens of thousands. During World War II, though the Japanese had burned many Chinese library collections, the Japanese collection at the National Library remained intact. In 1949, the National Library had a total holdings of 1,400,000 volumes of books and journals of which 292,162 volumes consisted of foreign language materials; this represented approximately 21% of the total collection.

In March 1950 the PRC changed the name of the National Library of Peiping to the National Library of Beijing. Beginning in 1978, when the PRC embarked on a reform policy, the national library began a major drive to modernize its facilities, equipment, functions, personnel, and organization. The goal of the government was to create one of the world's foremost national libraries. In 1988

after a new building was opened, the State Council approved a name change from National Library of Beijing to the National Library of China. (NLC—*Zhongguo Guojia Tushuguan*).

Following the establishment of relations with the United States and other foreign countries, beginning in the 1970s, the national library's collections increased rapidly. The Library found it could no longer accommodate all the incoming materials. In March 1975, after a proposal from Premier Zhou Enlai, the State Council approved the building of a completely new National Library adjacent to the Purple Bamboo Park in Beijing, in an area where many colleges and research institutes were located. The building plans were to reflect China's large population, long history, rich cultural heritage, and many nationalities. Construction of the new library building began on November 18, 1983, an undertaking involving more than 5000 workers. Completed on July 1, 1987 the new building is one of the largest libraries in the world. It has a total of 170,000 m² of floor space, which can accommodate 30 reading rooms with a seating capacity of more than 3,000 and the capability of receiving 7,000–8,000 readers per day. The old library continues to serve as a branch library for books published before 1949.

As the most noted library in China (under the Ministry of Culture) the NLC has the largest collection of Chinese books in the world; through legal deposit, it continues to comprehensively collect all books currently published in China. As of 2007, the NLC's collection consisted of the following: 6,379,096 Chinese books; 3,410,844 foreign books; 50,283 Chinese periodicals; and 43,407 foreign periodicals. It ranked fifth among national libraries in the world. The Library holds a rich collection of 270,000 volumes of rare books [rare books include the volumes of the Song (960–1279 A.D.) and Yuan Dynasties (1271–1368 A.D.) as well as volumes of rare books and manuscripts of notable authors]; 1,600,000 volumes of general ancient books [ancient books consist mainly of thread-bound books after Qianlong Emperor in the Qing Dynasty (1644–1911) and some collections in the Yuan and Ming Dynasties (1368–1644 A.D.)]; and 35,000 pieces of the scripted turtle shells and animal bones from the Yin-Shang Dynasty, ca. 1600–1046 century B.C. In addition, the NLC has the largest collection of foreign language publications in China. Similar to national libraries throughout the world, NLC serves as a depository library for UN publications; NLC also collects publications of other international organizations and foreign governments. It also acquires numerous microforms and AV materials, hundreds of CD-ROM databases, and more than 8000 titles of electronic publications. Like other national libraries, NLC represents an important cultural institution in China, for it has promoted exchanges and cooperation with libraries and cultural institutions all over the world. It has publications exchange relations with more than 1000 libraries and academic institutions in more than 120 countries and regions of the globe.

The NLC is not only a national repository of Chinese and international publications, but also a national bibliographic center, a national center of library information networks, and a library research and development center. In addition to serving the central government, research institutions, academic institutions, business, and the general public, the NLC plays a leading role in standardization, digitization, and networking efforts in China. With the use of modern technology, various kinds of bibliographical databases and subject databases were being created and improved. These include:

- The China National Bibliography Retrospective Databases (1949–1987), created by NLC and other cooperating libraries.
- The China National Bibliographical Databases (1988 to date) created by NLC.
- The China National Bibliographical Database (comprised of the two databases above).

In addition, the Online Computer Library Center (OCLC) becomes a center for creating, processing, and distributing bibliographical records, providing MARC records of Chinese books to scholars throughout the world. The NLC will add its bibliographic records to the OCLC WorldCat database, by developing software to convert the format of its records. It was expected that some 1.5 million records will be sent to OCLC by 2008. (<http://www.oclc.org/news/releases/20085.htm>). The Library will continue to add records beyond 2008 once the format has been converted. Through these activities, the NLC forms the center of a system covering the entire country. Administratively the NLC is under the PRC Ministry of Culture, which also supervises all public libraries—including provincial, municipal, county, and cultural center libraries.

Similar to libraries in the West, NLC divides its reference services along subject specializations: Social Sciences Reference Service, Sci-Tech Reference Service, Legal Information Reference Service, Abstracts and Indexes Reading Room, and Information Service. There is also a Newspaper Clipping Center and a Document Supply Center that provides subject research, document delivery, and photocopying service. NLC also has two main electronic reading rooms, the largest of their kind in China. These rooms were opened to the public in March 1995, which provided electronic information access services to readers—resources include CD-ROMs (as of 2005, there were 22,429 CDs) on various subjects, multimedia CD-ROMS, CD-ROM bibliographic databases, Web-databases, and over 10,000 full-text e-journals in Chinese or English. The users can phone, write, or visit in person. Service to the users includes training on the Internet, CD-ROM retrieval, and Web page design. The CD-ROM network in the electronic rooms is connected to all major information networks in China: 1) the network of exchange data of the People's Liberation Army (PLA); 2)

by wireless with the network of the Ministry of Posts and Telecommunications; and Military Medicine Academy; and 3) by phone with more than 10 institutions' network such as Nankai University Library at Tianjin, Life Science Institute of Beijing University, Zhejiang University, Zhejiang Industry University, Shanghai Huadong University of Science and Engineering, Xi'an Institute of Foreign Language, Ningbo Science and Information Technology Institution, and many more. These connections provide information exchange with all major institutions in China, the Internet, and remote access services for users around the world. With the Gigabit Ethernet library-wide network and an Internet service system open 24 hr a day all year, NLC is able to provide electronic information services, such as Internet Navigation, Full-Text Books Online, and OPAC Access. The NLC has become a center of network information resources. Furthermore, with the advanced Gigabit Ethernet technology developed in February 1999 and the opening of NLC Web site, the library has become a major network resource center connecting with high speed 100 MB leased lines to the State Council, Peking University, and Tsinghua University and also connecting ChinaNet, CERNet (China Education and Research Network), CSTNet (China Science and Technology Network), Beijing Cable TV Network, the National Cable TV Network, and CNC (China Netcom).^[12]

While the NLC adapted many modern library concepts and practices from the West, it also strove to utilize these practices to maintain the cultural heritage of China by preserving the great books of the past. The Library has maintained China's rich culture by preserving the books of the past, including works from the royal collection of the Southern Song Dynasty of the twelfth century as well as the Dunhuang manuscripts, the valuable Zhao Cheng Zang (the collection of Buddhist Scriptures preserved in Zhao Cheng County, Shanxi Province), the monumental Yong Le Da Dian (the Yong Le Encyclopedia), and the multivolume Si Ku Quan Shu (Complete Collection of Four Categories of Literature), all regarded as unique copies in the world. Along with the rare books and special collection, NLC maintained about 2,000,000 volumes of thread-bound books. Emphasis is placed on preservation and conservation of the library's exceptionally rich cultural heritage; staff members are engaged in restoration and conservation of rare books, applying traditional rare book conservation techniques and modern microfilming technology.

Since 1995, NLC has been keeping up with the latest development in digital libraries. In 1998, the Ministry of Culture approved a new building project "China National Digital Library." The project proposal of NLC Phase II and the National Digital Library of China Project was completed in November 2001. *The Feasibility Study Report on the National Library of China Phase II and National Digital Library of China Project* was approved by the State Planning Commission in 2003; 12.23 billion Renminbi (RMB) was distributed to NLC for the project;

in 2003, the RMB exchange rate was 8.3 to US\$1. Construction was completed in June 2008 and the Library was opened to the public on September 9, 2008. The National Digital Library of China has developed newer models of services, has become a center of Internet knowledge, and a base for information service without limitations of space and time. NLC provides unlimited digital resources, such as digital television, handheld mobile electronic reader for walk-in readers, E-government network, special area and equipment for the visually impaired, satellites, CDs, etc. Architecturally, the new building represents ideas of the past, present, and future: more open reading rooms, free access to publications, spacious reading areas, quiet areas for research, and modern exhibition and instruction areas.

The new library can accommodate an average of 8000 readers per day, with a collection capacity of 12–14 million volumes. The total floor space amounts to 80,538 m² and 2,900 seats. The total area of the National Library including both old and new buildings is 250,000 m², ranking it third among the world's national libraries.^[13]

Academic and Research Libraries

In the 1950s China's educational system, which had been modeled after the Western educational institutions, was reoriented toward using Soviet teaching techniques, curricula, textbooks, and materials. Beginning in the 1950s, higher education came under new directives, with its primary goal being the socialist reconstruction of China. Foreign policy, too, dictated China's educational practices and orientation; the Soviet "model" was widely adopted. Translations from Russian works on library science flourished and Soviet librarians were invited to visit China to consult and give lectures. Academic libraries were called on to engage in national development, subject to the same ideological and political constraints and requirements as other institutions. For example, purchase of Russian books exceeded those of other Western publications during the 1950s. However, a severe setback occurred during the Cultural Revolution (1966–1976) when all university libraries were isolated from the outside world. Foreign acquisitions ceased, creating a 10-year hiatus in book and periodical acquisition.

When universities and colleges finally reopened in 1978, academic libraries recovered and adapted many of the new Western ideas and practices of library science and technology. After the introduction of economic reforms and the opening of China in the 1980s, Chinese libraries developed rapidly. Academic libraries in China were rebuilt, transformed, and modernized and began to play a key role in national development. In the twenty-first century, many Chinese colleges and universities have the best-organized and finest collections. Examples of the development of academic libraries can be seen in Peking University Library (PUL) and Tsinghua University Library.

Peking University Library (PUL)

PUL was first established in 1902, under the name of Capital College Book Storage; at that time it had a core collection of 78,500 volumes. After the revolution of 1911, the present name was adopted. (Peking University kept the name Peking, because of its historic past. It was founded over 100 years ago and was the cradle of the 1919 May 4th Movement.) The reorganization of Chinese colleges and universities was initiated in the 1950s, following the founding of the PRC; PUL absorbed the Yenching University Library as well as collections from other universities. In 1998 when the construction of the new library building was completed, PUL became the largest academic library in Asia, with over 51,000 m², 4,000 seats in its reading rooms. By 2002, the centennial anniversary of PUL, the library contained approximately 6.5 million items and was ranked as the largest of any university collection in China. Its holdings included works in the fields of liberal arts, natural sciences, applied sciences, and social sciences. In addition to 2,700,000 volumes in Chinese, the library also holds 900,000 volumes in foreign languages as well as CD-ROMs, microforms, AV materials, and databases for many disciplines. PUL has been steadily developing its collection, with an increase of 80,000 items annually and it maintains exchange relationships with more than 500 foreign libraries, schools, and research institutes.

With a history of more than 100 years of collection development, PUL's Chinese rare book collection is ranked first among academic libraries in China. Among its treasures are 1,500,000 traditional thread-bound books. In addition, the PUL holds 56,000 copies of Chinese rubbings from inscriptions on ancient bronzes and stone tablets. These rubbings are very important for the study of ancient characters, calligraphy, and fine arts (Fig. 2).

On the cutting edge of technology, PUL operates the UNICORN-integrated automation system that includes an online public access catalog (OPAC), as well as modules for the acquisitions, circulation, reference, serials control, acquisitions, etc. In 1998, the headquarters of the China Academic Library Information System (CALIS) was established at the PUL. CALIS is a nationwide academic library consortium with members throughout 27 provinces, cities, and autonomous regions in China. Funded primarily by the Chinese government, its purpose is to digitize resources and develop an information service network in order to serve multiple resource-sharing functions among the participating libraries; these functions include online searching, interlibrary loan, document delivery, and coordinated acquisitions and cataloging.^[14]

Tsinghua University Library

Tsinghua University Library was founded in 1912 in Beijing, 1 year after the university was built. In 1928 the

Fig. 2 Peking University Library, Beijing.

Tsinghua School became the National Tsinghua University. Between 1928 and 1935 the Tsinghua University Library expanded rapidly. In 1931 the collection held 300,000 volumes and the library building was 7,700 m², with 700 seats. During the Sino-Japanese War (1937–1945) the University moved to Kunming. In 1938 Tsinghua University merged with Peking University and Nankai University to become the Southwest Associated University. The Tsinghua Library shipped 23,000 volumes to the new university. During the move, 10,000 volumes which were temporarily stored in Chongqing were damaged by Japanese bombings, and only 3,000 volumes were saved. In Beijing, the library building became a Japanese military hospital. By 1946, the collection returned to the original campus in Beijing, but the Library had lost 175,000 volumes during the war. After the PRC was established in 1949, there was restructuring which included a reexamination of its collection development policy to support the University's mission of education and research. While there was a strong focus on engineering materials, the library also collected literary works and other subjects in the humanities. The library's collection had grown to 1.35 million volumes by 1966. During the Cultural Revolution period, 1966–1976, the budget of the Library was cut deeply. However, with the help of faculty members, students, and librarians the majority of the library collection survived that tumultuous period. The collection since 1978 grew rapidly reaching 2.5 million volumes by 1990 (Fig. 3).

When the new library was built in 1991, a new stage in library development began. Since then, Tsinghua University Library has made substantial progress in automation and networking. The new library has a floor space of 39,000 m² and more than 2,500 seats for patrons. The Library maintains a rich collections of 3,923,000 volumes (books and journals) which cover the humanities, social

sciences, and management, but there is primary emphasis on the natural sciences, engineering, and technology. The printed collections contain: 300,000 thread-bound ancient books; over 4,000 current serials and more than 400,000 bound periodicals; over 30,000 Tsinghua University dissertations and theses; and 70,000 microforms. In addition the library has special collections of antiques and rubbings from inscriptions on ancient bronzes and stone tablets; it also contains manuscripts and videotapes donated by faculty members, staff, alumni, and others.

An advanced information infrastructure has been established. The CD-ROM network provides students and faculty with the literature and information searching services via the campus network. An increasing number of electronic resources and virtual resources have been made available in the library or online. Tsinghua University's virtual library is a network of information databases including approximately 42,000 full-text e-journals; over 350 electronic databases; more than 920,000 e-books; more than 35,000 multimedia collections (not including online databases and Internet resources). The system supports the university's goal of becoming a world-class institution.

Tsinghua University Information Network Engineering Research Center was established in June 1994 as an engineering research entity that includes Computer Science and Communication. The center has completed "Sample Project of CERNET (China Education and Research Network)" which was undertaken jointly by Tsinghua and nine other well-known Chinese universities. The first CERNET in China to adopt the TCP/IP system structure was also established here; its aim was to provide a common communication platform for information exchange, scientific computing, and international networking for China's universities and schools. The center served as an important base for the state computer and Internet technology research.

Fig. 3 Tsinghua University Library, Beijing.

Subject librarian system. Tsinghua University Library has a Reference and Information Service Desk at the main hall of the new building in order to provide assistance and advice to individual library patrons. In addition to helping the faculty and students make better use of library resources, the librarians have also attempted to strengthen ties between library and academic departments through "Subject Librarian System," which was begun in 1998. Since then, every academic department has appointed a departmental library coordinator to keep the library apprised of the needs of the department. The subject librarians have academic credentials related to the discipline of the department which they serve. The responsibilities of the subject librarians include:

- Offering training programs to new faculty and new students in March and September of each year.
- Conducting customized workshops on library utilization for their department.
- Introducing new information resources and new services to their department.
- Collecting and introducing useful Web resources for their department.
- Soliciting information in regard to the needs of their department for journals, books, electronic resources, and services of library.

Public Libraries

The public libraries of cities, counties or districts, and villages are all supervised by the Ministry of Culture. They play an important role by enabling Chinese citizens to obtain cultural and educational information as well as meeting the needs of economic construction and scientific research. Some function as research libraries. Organizationally, public libraries are under the Ministry of Culture and are not centrally controlled except for the NLC. They are mainly self-governed and self-financed through the Bureau of Culture of their respective governmental level. At the local level, this consists of provincial regulations characterized by regulations of the operations and organization of libraries in cities, counties, towns, and villages.

For the year 2005, Tables 1–3 provide an example of the number of public libraries and the size of their collections and staff. Table 1 gives the total number of libraries, staff, and collection at the national, provincial, municipal, and counties level in China. Tables 2 and 3 provide examples of major municipal and autonomous regions/

Table 1 Chinese public libraries 2005.

Categories	Number of libraries	Staff	Collection
National	1	1,372	25,050,000
Provincial	38	7,706	143,555,000
Municipal	338	12,704	120,548,000
Counties	2385	28,641	191,407,000

Table 2 Major Chinese municipal public libraries 2005.

Municipality	Number of libraries	Staff	Collection
Beijing	25	1219	11,214,000
Chongqing	43	755	7,675,000
Dalian, Liaoning	12	461	4,675,000
Ningbo, Zhejiang	12	228	2,641,000
Shenzhen	8	444	4,464,000
Tianjin	32	1057	8,694,000
Qingdao, Shandong	13	267	3,294,000
Xiamen, Fujian	8	153	1,925,000

Source: From Ref.^[49]

provincial libraries with the number of libraries, staff, and collection.

Official statistics for township and village libraries (rural libraries) do not exist; however, scattered evidence seems to indicate that this particular class of libraries expanded greatly. In Hunan Province, the number of township and village libraries grew from 1,800 in 1985 to 14,000 in 1997.^[15] Starting in the 1980s with the surge of economic reforms, public libraries at all levels regarded economic development as the main feature in their work. For example, in rural libraries, public libraries collected and published works on the production technology of planting to be sent out to peasants. These public libraries delivered books by bookmobile or mobile book store and set up service points for circulating books.

Shanghai Library

Established in 1952, the Shanghai Library is the second largest public library in China, next to the NLC. In 1995 the Shanghai Library merged with the Institute of Scientific and Technical Information of Shanghai (ISTIS) (*Shanghai Kexue Jishu Qingbao Yanjiusuo*). In 1996, the

Table 3 Major Chinese autonomous regions/provincial public libraries 2005.

Location	Number of libraries	Staff	Collection
Anhui	88	1217	8,474,000
Fujian	84	1110	12,735,000
Guangdong	129	3252	31,194,000
Hebei	153	1690	13,071,000
Heilongjiang	96	1669	12,910,000
Henan	136	2742	14,292,000
Hunan	120	1963	16,665,000
Inner Mongolia	110	1776	7,435,000
Jiangsu	103	2363	31,785,000
Liaoning	126	2888	23,256,000
Shaanxi	111	1691	8,870,000
Shandong	145	2690	27,464,000
Sichuan	141	1869	20,023,000
Tibet	4	62	421,000
Qinghai	43	365	3,242,000
Xinjiang	96	951	8,174,000
Yunnan	149	1661	13,709,000

Source: From Ref.^[49]

new institution moved to its new quarters on Huai Hai Zhong Lu. It is now a comprehensive research library as well as a public library. The Shanghai Library together with the ISTIS has holdings of approximately 51 million items. The location covers 3.1 hectares of land, with a floor space of 83,000 m². The architectural design comprises of two towers connected by a glassed-in-walkway; the taller tower is for sci-tech holdings, the other for social sciences and humanities. Within the social sciences-humanities building is a glass-enclosed atrium crisscrossed by escalators leading to different floors (Fig. 4).

The merger of the Shanghai Library and the ISTIS has established the Library as a center of information resources, an information clearinghouse, and as a center for lifelong literacy. After reorganizations, a new three-dimensional model of services has emerged:

1. Service to the general public—The Library's public services include, reading and lending, reference service, public lectures, exhibitions, and cultural meetings. The policy is to have the Library open to everyone (people outside the city can get a temporary pass with an ID card) and open everyday. The Library maintains 21 local branch public libraries (they share the same circulation system and overall resources). The Shanghai Library has a municipal network of four-level public libraries: 33 district libraries, 215 community/township public libraries, and thousands of local/village reading rooms. In addition, the Shanghai Library serves as a coordinator among all kinds of

libraries and information services in the city; there is a consortium of 60 research libraries. This is an indication of the role of the Library's mission to reach out to the people.

2. Service to the research community—Reference service for the city's social and industrial development is provided by both the Shanghai Library and ISTIS. With the Institute's over 100 specialists in various scientific and technical subjects, the Library has organized information research think tank projects for the industrial and technical community.
3. Service to the city government and legislature—Since 2001, the Library has successfully served the city government and legislature, by producing bulletins in two series: General and Technology. This enriched service has been well received because of the information on city development, comments from noted experts, and new trends in world economy and technology. Since the service was so well received, the government has assigned the Library numerous research projects.

The library's mission is to pursue excellence through service. The library has a user-centered policy and sponsors outreach activities to the public. Through their combined collections, the Shanghai Public Library and the ISTIS respond to the educational, social, and industrial needs of the city. The historical documents in the collection include 100,000 manuscripts and letters, approximately 5,400 local records dated before 1949, 18,000 titles of

Fig. 4 Shanghai Library, Shanghai.

genealogical files (342 family names), 150,000 pieces of epigraphs and rubbings, and 1.7 million ancient books (25,000 titles amounting to 170,000 volumes are rare editions). There are more than 50,000 letters, diaries, inscriptions, pictures, and rare documents from famous people of the late Qing Dynasty; and many of these items are being digitized. Materials in the collection range from ancient artifacts, such as those described above, to the latest technical reports, patent files, sound and video recordings, and digital databases. As many as 1 million books are displayed in its 25 reading rooms and open stacks.

With the twenty-first century being the information era, Shanghai Library is giving priority to the building of a digital library. Nine digital reference services have been established: Shanghai Classical Pictures, Shanghai Classical Texts, Music Station, Ancient and Rare Books, Books of the Republic of China (1911–1949), Database of Index of Papers presented at Chinese Professional Conferences, Chinese Newspapers and Periodicals, Foreign Periodicals, and Science and Technology Garden.

School Libraries

After 1949, the development of school libraries became a priority of the Chinese government. School libraries together with academic libraries were under the Ministry of Education (from 1985 to 1998 called the State Commission of Education). Between 1949 and 1965, the number of school libraries multiplied in every province, region, and municipality. In 1989, the State Commission of Education held a national conference on school libraries and a Preparatory Committee for the National Association of Primary and Secondary School Libraries was formed to oversee their development at the local level. In 1991 the Committee issued an official document, *Regulations on School Libraries*. Since then, each province has issued its own provincial rules in accordance to its specific local conditions.

In addition to libraries managed by cultural and educational departments of the central and local governments, there were libraries and reading rooms for children run by Trade Unions. It was estimated that in 1989, there were more than 200 children's libraries or reading rooms established by neighborhood service centers in Beijing, Tianjin, and Shanghai. Also book dealers had set up private libraries, reading rooms, and lending deposit stations to provide an important service to children living in rural areas, in the expectation that the Ministry of Culture and other departments would provide support to these new libraries and help train librarians. Taken as a whole, the development of the school libraries was uneven. There were great differences in areas, given the economic, cultural, and educational level of developments. Over 80% of those schools that had libraries were chiefly located in large and medium-sized cities along the coast. In the economically backward areas of the West, with a low level of education

70% of the schools had not yet established any libraries. This uneven distribution of service was one of the major problems in the growth of school libraries in China.

In China there are also primary and high schools belonging to universities. In May 2007, author visited Xibei University (Xian) Elementary School library and interviewed Headmistress Sun Shu Min. At Xibei University (Xian), there is a provincial university primary school with 1600 students whose families are members of the faculty and staff of the university; others from the province who wish to enter were tested and carefully selected. According to Sun Shu Min, the school's goal was to emphasize reading ability. Each month there was a contest to see which class read the most books, and a prize was awarded to the winning group. On each of the four floors of the school there was a reading corner where students could sit and read various children's magazines. Other incentives to encourage reading are the regular reading discussion groups and parent–teacher conferences. Since 2000, an electronic room was also being used for classes; it was there students learned to use the computers. The annual library budget was approximately 20,000–30,000 yuan in 2007, emphasizing the purchase of electronic books. There was an audiovisual room which included a television set, videos, a language lab, and other facilities. However, the library had no set hours and there was only a part-time staff member to maintain the collection.

Special Libraries

Prior to 1949, research in China was mainly conducted in universities. After the establishment of the new government, it reorganized scientific research according to the Soviet system, which meant that the sole function of universities was teaching. From then on, research was to be carried out in specialized units such as the Chinese Academy of the Sciences (*Zhongguo Kexueyuan*) and Chinese Academy of the Social Sciences (CASS) (*Zhongguo Shehui Kexueyuan*). To support research, special libraries were set up under the jurisdiction of the government agencies and institutions: libraries of the Academy of Sciences (natural sciences) and libraries in the respective research institutions under the academies. There were also libraries in the various ministries or commissions of the government such as the ministries of geology, medicine, agriculture, and industry as well as their numerous branches. As examples of such libraries, two of the research units of the Academy of Social Sciences Library will be discussed: the Institute of Law Library (ILL) and the Institute of West Asian and African Studies Library.

Chinese Academy of Social Sciences (CASS) Library Center for Documentation and Information

In May 2007, the author visited the Chinese Academy of Social Sciences Library and interviewed Jiang Ying,

Deputy Director of the library. The CASS was founded in 1977; prior to that time, CASS evolved from the Research Division of Academic Information, Department of Philosophy and Social Sciences under the Chinese Academy of Sciences in the late 1950s. The Division was later named Division of Academic Materials. From the Division, the Institute of Information of the CASS was founded in 1977. In October 1985, the Center for Documentation and Information (CDI) emerged as a result of the amalgamation of the Institute of Information and the Materials Division. In 1994 the Chinese Academy of Social Sciences Library (CASS Library) (*Zhongguo Shehui Kexueyuan Tushuguan*) was founded. A new library building was constructed in 2002, covering an area of 18,000 m². The CDI (*Wenxian Qingbao Zhongxin*) is a part of the CASS Library.

The CASS Library has not only applied the most advanced computer and network technologies for researchers in the institutes but also for other scholars. However, the CASS Library is not open to the general public. The library collects, catalogs, shelves, and loans primary documents for researchers in the humanities and social sciences. The emphasis is on collecting in the areas of economics, sociology, and international studies. The collection is almost evenly divided between Chinese and English language materials. The CASS Library has approximately 5,000,000 items; this includes 2.4 million volumes (journals and books), covering all areas of the humanities and social sciences in more than 40 languages. Other items in the collection include:

- Thread-bound ancient books 650,000 vols.
- Paperback books 880,000 vols.
- Foreign books 410,000 vols.
- Academic degrees theses 100,000 vols.
- Bound-volumes of newspapers and periodicals 300,000 vols.

In the early 2000s, the collection consisted of 1800 Chinese and 900 foreign language periodicals, in addition to 1780 literary journals published from 1919 to 1949.

A series of CD and online databases are also available; they include: Bibliographic Database of CASS and Database of Citations of the Humanities and Social Sciences in China; Full-Text Database of the People's Daily for over 50 years; Full-Text Database of Duplicated Newspapers and Journals of the Renmin University of China; Gale's (United States) Database of Full Texts and Abstracts in the Social Sciences, and 13 other databases of OCLC. The budget has grown to accommodate the need for electronic resources. In 2007, the budget for electronic resources was 2,000,000 yuan as compared with 8,000,000 yuan for books. CASS actively engages in exchanges with institutions and academic organizations in Russia, United States, Great Britain, France, Germany, Holland, Finland, Japan, R.O. Korea, Vietnam, Israel, Taiwan, Hong Kong, and Macao. Annually foreign books acquired through

exchanges account for 20% of the total acquisition of foreign books.

Institute of Law Library (ILL) of the CASS

In May 2007, the author visited the ILL of the CASS and interviewed Zhang Qun of the Institute of Law. Established in 1958, the ILL (*Faxue Yanjiusuo Tushuguan*) of the CASS is considered the preeminent law library in China. The Library's collection was mainly acquired from three sources:

1. Tsinghua University in 1958 when universities were restructured.
2. The Legal Bureau of the State Council and the Legal Press in 1959.
3. Donations of nationally and internationally famous jurists.

After 1959 the Library has grown through purchase, exchange, and donations, becoming the largest and most comprehensive legal library in China.

In 2007 the total area of the Library was approximately 1127 m². Eight hundred thirty-five square meters were used for Chinese books, books in western languages, Japanese books, ancient books, journals, and newspapers. The reading rooms occupied 210 m², including separate reading rooms for newspapers (Chinese and foreign languages), reference books, Chinese data, electronic data, and catalogs.

The law collection includes theories of law and various branches of legal sciences. The main emphasis is on legal history, laws and regulations from various countries, and international and domestic literature on every aspect of law. At the end of 2001, the library's holdings contained 385,000 titles; of the 177,000 Chinese books, there were 38,227 ancient legal books and documents, of which 2,795 were rare and solely existing copies. In addition, the library holds over 60,000 foreign language works, including books in English, Japanese, Russian, French, German, and many other languages.

In this foreign language collection there are a large number of modern Japanese legal texts and materials on human rights in English. The library also has 25,000 journals (17,000 in Chinese and 8,000 in foreign languages). The collection also includes 24,193 pages of English books on microfilm, as well as 110,000 Chinese newspaper clippings on law. In 2006, the budget was 600,000 yuan, which was mostly spent on printed books. Few foreign books were purchased because of the high inflationary rates. Even the purchase of e-journals became difficult, therefore, the CASS database network was utilized.

The library provides various services to the legislative, administrative, and judicial sections of the state, the legal practitioners and law school professors, and students, but it does not offer interlibrary lending services. There were

eight professional staff in the library, five had library science degrees, and three had law degrees.

Institute of West Asian and African Studies Library of the CASS

The Institute of West Asian and African Studies Library (IWAASL) (*Xiyafeizhou Yanjiusuo Tushuguan*) of the CASS, established in 1981, is considered the best library in African collections in China. In May 2007, the author visited the IWAASL of the CASS and interviewed Chen Hong, Librarian and Chen Yulai, Deputy Director of the Center of Southern African Studies of IWAAS. There are more than 20,000 books, one-half relating to the Middle East and the other half to Africa. The library subscribes to over 100 Chinese journals, as well as more than 100 English and a few French language journals. Most of the budget is spent on foreign journals (70%), with few books purchased from overseas. The remaining 30% is for Chinese newspapers and some Chinese books. The library subscribes to no overseas newspapers, due to high costs. The budget was little more than 300,000 yuan in 2007.

Ms. Cheng Hong, librarian of the IWAASL, created several magazine and book databases for IWAASL:

- The Chinese academic journal database, which is an index for articles relating to the Middle East and African studies.
- The database for Western language magazine articles on Middle East and African studies, began in 1983, which includes indexing and some abstracts.
- Full-text databases for Chinese articles began somewhere between 1990 and 2001.
- The book database which includes abstracts of books published in China and abroad on the Middle East and African Studies.

The CASS database network contains other works not found in the IWAASL. The Institute has a separate room with compact shelving for the 20,000 plus collection. The materials are shelved in two sections, Africa and the Middle East, with half of the materials in Chinese in each area.

Digital Library Collections and Services

During the past decade, the information infrastructure of China has expanded greatly. According to the China Internet Network Information Center (CNNIC) Survey, June 30, 2007, there were 162,000,000 Internet users and 1,311,600 Web sites. A majority of the Internet users live in the capital and coastal cities, which is where the major universities and scientific research institutions and industries are located; these cities are also centers of research and development activities. With increased access to the Internet, the development of digital libraries in China has become a priority and a significant component in the

national information infrastructure. Digital libraries in China are defined as

research institutions where computer specialists and content service providers focus on technology improvements for digitizing, organizing, distributing, preserving, retrieving, and searching data, or as projects with practical applications designed to create digital collections or provide digital library services.

After the 1996 IFLA Conference held in Beijing, the first national level digital library project in China, the National Pilot Digital Library Project (NPDLP) was initiated in 1997 by the Ministry of Culture and the State Planning Commission. The NPDLP included the NLC and five large public libraries (the Shanghai Library, Liaoning Library, Nanjing Library, Zhongshan Library, and Shenzhen Library). The project's aim was to experiment a digital system of collaboration and resource sharing with participants. Since 1998 many additional research and development projects related to digital libraries have been launched by universities (under the Ministry of Education) and by the science and technology research institutes and the Chinese Academy of Sciences.^[16]

Chinese National Science Digital Library (CNSDL)

The CNSDL began in 2001 and was part of the Knowledge Innovation Project of the Chinese Academy of Sciences. The primary goal of CNSDL was to build a national information resources and management system that would provide a document delivery and interlibrary loan service system accessible from every scientist's desktop in China. CNSDL has also constructed several Chinese scientific literature databases with more than 1 million records, covering major topics in chemistry, biology, physics, mechanics, optics, mathematics, astronomy, geography, and computer science. CNSDL provided more than 10,000 full-text foreign scientific magazine and other virtual reference services.^[17]

China National Knowledge Infrastructure (CNKI)

Established in 1996, the CNKI is a significant national e-publishing project in China. This project was founded by Tsinghua University that developed the Tsinghua Tongfang Knowledge Network Technology Company. The CNKI full-text databases reach out not only inside China, but also globally, covering resources such as journals, newspapers, dissertations, proceedings, yearbooks, reference works, and others. CNKI has been a great encouragement for Chinese libraries to digitize as well as to aid researchers. As of 2006, the CNKI academic databases have served more than 5500 universities, public libraries, and other research institutions.^[18]

World Digital Library (WDL)

Developments in digitization are progressing in China. On November 2008, the LC signed an agreement with the NLC to collaborate in developing the WDL, which included: to provide content to the WDL in such areas as the development of the Chinese-language interface; to set up international working groups to plan the project; and to establish an advisory committee of leading scholars to suggest major collections relating to the Chinese culture and history in the WDL. Signing took place between Zhan Furui, General Director, NLC and James Billington, Librarian of the Library of Congress. The goal is to digitize important primary Chinese materials, including manuscripts, maps, rare books, musical scores, recordings, films, prints, photographs, architectural drawings, and many more; to provide important resources on the Internet to scholars; and to promote international understanding.

The background to the WDL began in October, 2007, when the LC and other institutions around the world, in collaboration with the United Nations Educational, Scientific and Cultural Organization (UNESCO) presented a prototype of the future WDL. Major institutions participating in the WDL included Brazil, Egypt, Iraq, Israel, Russia, Serbia, and Sweden; also included were the U.S. National Archives and Records Administration, the John Carter Brown Library, and the libraries of Brown and Yale Universities. The project is to be launched in April 2009.^[19]

Peking University Library (PUL) Providing Virtual Reference

PUL has been in the forefront of the development of a modern digital library. When the library launched its virtual reference service in 2002, it adopted OCLC's QuestionPoint, a collaborative reference system using technology that can handle the complexities of the Chinese language and easy to use. Question Point allows libraries to reach out to patrons, instead of waiting for the patrons to come to the library to ask questions. PUL has a well-trained reference staff and has developed clear guidelines and effective implementation plans. Question Point has an interface that enables libraries to offer online reference services locally and to refer questions to libraries locally, regionally, or globally.

Since 1998, PUL Library has served as the administrator of the CALIS, which includes over 60 academic libraries as members; these members collaborate within China to share cataloging information and library resources. In 2007, collaboration in digital reference service was limited, since only five CALIS members used Question Point; these libraries included Peking University, Tsinghua University, Shanghai Jiaotong University, Sun Yat-Sen University, and Beihang University. In the future CALIS

would like to plan its own collaborative digital reference system for academic libraries in China.^[20]

Digital library projects in China continue to be developed. The concept of a digital library was first introduced in China at the IFLA Conference in 1996, which was held in Beijing. China has made much progress, but more remains to be accomplished.

Library and Information Science Education

Formal library training in China began in 1920 when a program was set up at Boone College, jointly founded by Mary Elizabeth Wood, Shen Zhu Rong, and Hu Qing Sheng. However prior to 1949, the development of library education was limited, due in part to the turbulent political situation. With the establishment of the PRC the entire concept of library service changed. The new government sponsored a great expansion of libraries as well as reconstruction of facilities that had been destroyed during the Japanese occupation and the civil war. The number of libraries grew from 400 in 1950 to more than 33,000 in 1958. To meet the growing demand for library personnel in the 1950s a new library education system was set up following the Soviet principle of dividing libraries and information services into two separate systems where by library study was a part of *literary* study and information science was regarded as the study of *science*. This separation between library and information science later turned out to be impractical.

The Department of Library Science at Peking University was created in 1949 and 3 years later the Boone library school was absorbed by Wuhan University, where it became a department of library science. At first Wuhan and Beijing both operated junior college level programs that offered high school graduates 2 years of professional training; later the programs were extended to become 4-year college degrees. However, in the 1960s the Cultural Revolution disrupted China's educational programs and formal education was halted. Universities did not resume regular instructions until the late 1970s.

College-level library education also became an important component in the library and information education system in China. Wuhan and Peking universities both had two divisions: one specializing in the humanities and social sciences and the other in science and technology. Students could enroll in a 4-year college program with a bachelor's degree and a 2- or 3-year certificate programs. Graduates of this degree program spent equal time in professional training and in other courses, such as liberal arts, social science, law, or computer science offered by other departments.

Beginning in the early 1980s, the entire political/education ideology in China shifted to a more pragmatic and open policy. Economic reform to further modernization became the rallying cry of the 1980s, and it soon became apparent that well qualified librarians and information

specialists were urgently needed. In 1979, the first 3-year master's program was created at the Departments of Library Science at Wuhan and Peking. In 2007 there were 18 institutions offering master's degree—9 were accredited to grant M.A. degrees in library science and the other 9 eligible to grant an M.S. degree in information science. Entrance exams were required for graduate education and general higher education. Students spent approximately one-third of the total course hours in internship and conducting research projects, and about the same number of hours in writing a thesis during the third year.

Since 1984, there have been other graduate programs which required only 2 years of course work and no thesis. Between the years 1978 and 1993 there have been approximately 700 graduates, primarily in the master's program. As of 1986, 18 of the government-recognized comprehensive universities had library and information programs, with more than 2000 new students enrolled annually. In 1989, there were 50 institutions that had developed departments with specialized programs for formal library and information courses.

The rapid growth of information industry has challenged educational institutions to update their curriculum and expand their teaching programs to meet new needs. In 1991, Ph.D. programs were first introduced at Wuhan and Peking universities and the following year the Department of Library Science at Peking University changed its name to Department of Information Management. The 3-year doctoral program at Peking University consists of coursework and a dissertation. In 2007, there were four institutions offering Ph.D. degrees: Peking University and the Chinese Academy of Sciences were qualified to confer the Ph.D. in library science, while Wuhan and Nanjing Universities were allowed to grant the degree in information science.

Informal education has developed rapidly and provided opportunities to deliver library and information education in remote regions such as Xinjiang and Inner Mongolia. These programs were offered to adults who had no formal degrees but worked in the library and information fields. Three types of programs were available: correspondence programs, television programs, and in-service training. The Ministry of Culture and the Ministry of Education declared that upon completion of the required courses, students could earn a college diploma or certification. The programs differed little from the formal 3-year certification education.

Night and "Spare-time" Schools, Workshops, and Seminars organized in metropolitan areas offer library education to tens of thousands of experienced library workers who lack formal education, but wish to take advantage of the opportunity to gain the basic knowledge of the library profession. The NLC set up the Sparetime Workers' College and Nanjing Normal College set up the Night College of Library Science. Conferences, workshops, and seminars were organized within libraries and others were held

jointly with the China Society of Library Science (CSLS). This has resulted in a great improvement in the quality of personnel.

Professional Associations

The LAC founded in 1925 was an important force for library reform during the 1920s and 1930s. In 1949, LAC moved with the Nationalist government to Taiwan and was inactive until November 1953 when it was reconstituted in Taipei.

In China there were no professional societies for 30 years. It was only until the "opening up" of China in the late 1970s did various professional societies reemerge. In 1979 The China Society for Library Science (CSLS), *Zhongguo Tushuguan Xuehui*, was established. Soon after international and bilaterally organized seminars were presented in China: a UNESCO-sponsored seminar was held in Beijing on the topic of automation and how to access databases. Seminars were organized by the CSLS with international agencies. International viewpoints were exchanged and discussed.

Though China was one of the founding members of IFLA (1927) it was not active in IFLA for many years due to war, political unrest, and the Taiwan issues. Slowly as China regained its membership in UNESCO, CSLS returned to IFLA in 1981.

As of 2000 the CSLS had 10,000 individual members and 47 institutional members. The CSLS is an affiliate institution of the NLC and a national association on librarianship under the joint leadership of the China Association for Science and Technology (CAST) (*Zhongguo Kexue Jishu Xuehui*) and the Ministry of Civil Affairs. Its functions as a liaison between the Government and librarians; it also has the status of a national nongovernmental and nonprofit organization. CSLS is a member of the China Association for Science and Technology and a consultative body of UNESCO. The CSLS guidelines and policies as set up by the state are to promote and contribute to the development of librarianship for the purpose of modernization. Its principle responsibilities as stated in the Constitution are to promote library science research; in addition the society has conducted seminars and training classes on particular topics. General membership meetings are held every 5 years.

A core national library journal sponsored by the CSLS and the NLC is the *Journal of Library Science in China*, JLSC (former name was the *Bulletin of the China Society for Library Science*, 1979–1990). JLSC presents the theoretical and practical results of research and development by professionals, professors, and students in the field. Since the establishment of CSLS, the number of professional journals has been growing. More than 50% of library and information journals published in China originate from library societies at the national, provincial, and municipal levels.

The English name of CSLS was changed in 2005 to the LSC. Annual meetings are conducted. At the 2007 annual conference in Lanzhou, Gansu Province, China, LSC invited members from the ALA and Chinese American Librarians Association (CALA), an affiliate of ALA, to participate. The main theme of the conference was “The Library: New Environment, New Changes and New Development.” Barbara Ford, former president of ALA, Director of the Mortenson Center for International Library Programs at the University of Illinois at Urbana-Champaign participated in the seminars. More than 50 presentations were conducted and over 20 discussion panels were conducted. Approximately 300 attendees from all over China came to the conference. The forums were very successful and the speakers were all well-known in their fields; it provided a learning exchange with Sino-American librarians.

After China’s return to IFLA in 1981, its activity with IFLA has promoted programs beyond its national boundaries. International exchanges, cooperation, and relationships with foreign library associations have all developed. In 1996, the 62nd IFLA General Conference was held in Beijing. The theme of the conference was the Challenge of Change: Libraries and Economic Development. The IFLA Conference gave librarians all over the world an excellent chance to exchange ideas and explore librarianship in China.

Other significant organizations for information professionals include the China Society for Scientific and Technical Information (CSSTI) (*Zhongguo Kexue Jishu Qingbao Xuehui*) and the Chinese Archives Association (CAA) (*Zhongguo Dang’an Xuehui*). The CSSTI was founded in 1964 and was a part of the CAST. CSSTI was a nongovernmental organization of science and technology professionals and its mission was to promote the development of information science and its services; to serve science, technology, and economic construction in China; to edit and publish information in books and periodicals, and to strengthen international academic exchanges.

ARCHIVES AND ARCHIVAL SCIENCE

The responsibility and overall direction of archival work in China reside in the State Archives Bureau (SAB) (*Guojia Tanganju*) which was established in 1954 under the State Council, the highest executive organ of the PRC. The main principles of archival work in China are to administer national records, to protect the safety of the records, and to facilitate the work of the state by making archival documents available. In other words, the role of the archives is to serve the priorities of the state. The main emphasis in Chinese archival study is on the dissemination of select documents centered on historical themes considered by archivists and historians to be significant in Chinese history.

Legislation

In 1987, the Archives Law was adopted by the Standing Committee of the National People’s Congress and enacted on January 1, 1988. It defined the establishment of archival administration and records department, the collection, utilization, and protection of archives. The Archives Law of the PRC allowed, but did not require, that records in state archives be opened to researchers 30 years after their dates of origin. Economic, scientific, technical, and cultural records may be opened earlier. Records that are highly confidential may be restricted up to 50 years or longer. The law also requires that records must first be processed, arranged, and described before they may be opened for consultation. The function of the SAB is to outline broad archival policies and principles for the entire nation, and to work in consultation with each national-level ministry to devise and institute archival management, records management, and records disposition guidelines for use by archival repositories at every level. Below the National SAB are archives bureaus at the provincial, municipal, and county levels.

Chinese Archival Classification

The Chinese Archival Classification (CAC) together with the Chinese Thesaurus for Archives and the Cataloging Guidelines for Archival Descriptions were first published in 1987 under the auspices of the SAB; a second edition appeared in 1997. Because classification schemes based primarily on subjects are not considered suitable for archives, the administrative structure of the government is used as the basis for archival classification schedules. The CAC has been adopted by archival institutions at all levels in China.

Archive Management Bureaus and Archival Repositories

It was reported in 1992 that there were more than 3400 archive management bureaus and more than 3500 archival repositories in China. What ties all these diverse entities together is the role of the SAB in Beijing and archives bureaus of the provincial and local governments. The role of the SAB is to create general archival policies and principles for the entire country, and in consultation with each national-level ministry to disseminate archives management, records management, and guidance for disposition of records for archives bureaus or archival repositories at all levels. The provincial level archives are responsible for the acquisition and preservation of local records. They function and receive guidance from the SAB. The SAB not only implements regulations and archival records management, but staff members go out to provincial archive bureaus to review, offer advice, and offer suggestions in improving local applications. Archival

repositories differ from archival management: the latter is concerned with policy management and the former with care and service. There are two kinds of repositories, comprehensive archives and specialized archives. Each performs at different levels, be it national, provincial, or local. A comprehensive repository houses all kinds of records from different units in a geographic area and a specialized repository is limited to keeping records in a special medium, for example, motions pictures, photos, audio and video recordings.

National Archives

The national archives in China are The First Historical Archives (in Beijing) and Second Historical Archives (in Nanjing). They are directly under the SAB. The Central Archives (in Beijing) contains contemporary records and those relating to Communist party history, and is directly subordinate to the State Council.^[21]

In May 2007, author visited the first Historical Archives of China in Beijing and interviewed Zou Ailian, Director. The First Historical Archives in Beijing was established in 1925 and was also known as the Ming-Qing Archives or the Palace Museum Archives; it was the most important historical archives in China for the pre-1912 period. The collection consists of records of the central governments of the Ming (1368–1644 A.D.) and Qing (1644–1911 A.D.) dynasties; it holds over 10,000,000 items (jian). Published reports estimate that more than 317,000 items in the First Archives collection were from the Manchu (Qing dynasty). There were at least 10 catalogs for different types of Manchu documents which have been made available to researchers. They contain valuable research materials on military affairs and relations with Mongolia, Tibet, and Xinjiang. The Archives have been used heavily by Chinese and foreign scholars. An extremely useful guide was published by the archives under the title *Collection of the First Historical Archives of China*, 1985 (*Zhongguo Diyi Lishi Dang'An Guan Guancang Dang'Angaishu*). Scanning, microfilming, and photocopying are available.^[22] There were 14 Divisions, 170 full-time staff, and 100 part-time employees in 2007. The Archives, since 1975, is housed in a modern building; 10% of its records are digitized. It is under the SAB.

The Second Historical Archives of China (SHAC) in Nanjing was the first archive to be established after the founding of the PRC. It is also under the administration of the SAB. The collection consists of original records of the previous central governments and their subordinate organs (Republic of China, during the 1912–1949 period). The Second Historical Archives was formally opened to scholarly inquiry in 1980; it now has state-of-the-art storage facilities, preservation programs, cataloging systems, and retrieval capacities. SHAC has five departments: 1) Archive Processing and Cataloging Department; 2) the Conservation Department; 3) the Public Services

Department; 4) the Technical Department; 5) the Computing Center; and 6) the Compilation Department. The aim of the SHAC is to collect, arrange, catalog, preserve, compile, and facilitate the use of the holdings of the Archives. The Archives are equipped with microfilming, photocopying, and computer technologies. Various types of finding aids are available. The SHAC has led the way in redefining the nature of a state archive by extending their holdings well beyond those of formal government bodies; the SHAC collection now includes papers of Republican-era institutions such as the private industrial companies, banks, and educational institutions that had been nationalized either during the Guomindang period or the early years of the PRC. By the end of 2000, the records of the Republican governments (and their subordinate organs during the 1912–1949) were estimated to comprise 1,800,000 files in more than 900 classes (Fig. 5).

The bulk of the holdings in the SHAC is made up of official documents; also included are photographs, medals, seals, currencies, postal stamps, trade marks, geographical handbooks, paintings, and calligraphy. These items are useful for historical research and verification of historical artifacts. Since SHAC was opened to the public in 1980, it has been used by approximately 300,000 researchers who have consulted more than 1 million files; these users are from China and abroad (Taiwan, Hong Kong, the United States, Japan, the United Kingdom, France, the Netherlands, and Germany). To make records more accessible to the public, the SHAC staff have published more than 50 different compilations of primary sources. The SHAC also publishes the journal *Republic Archives* relating to historical sources held at the archives.^[23]

Provincial Archives

The archives of provinces, autonomous regions, and municipalities take their directions from the respective provincial, regional, or municipal governments. While the SAB offers advice, it does not manage or administer the local archives. An example is the Sichuan Provincial Archives (*Sichuan Sheng Dang'an Quan*). In May 2007, author visited Sichuan Provincial Archives in Chengdu and interviewed Feng Shaocheng, Director of Circulation. The Sichuan Provincial Archives was established in 1966, but it was dispersed during the Cultural Revolution; it resumed activities in 1979 and moved into a new building in 1988. The total collection consists of approximately 1.3 million files, making it one of the largest provincial archives in China. The emphasis is on the Qing Dynasty, the Republican and contemporary periods as it relates to Sichuan. All of the documents of the Qing Dynasty are on microfilm, but as of 2007 documents from the Republican and contemporary periods had not yet been microfilmed. The Sichuan Provincial Archives does not collect any new materials on Chongqing (in 1990, Chongqing became a separate administrative district directly under the national

Fig. 5 The Second Historical Archives of China, Nanjing.

government of China, therefore, is no longer part of Sichuan) or any separate files on warlords and military matters. The Ba-xian county archives during the Qing period (1644–1912) are the most comprehensive collection of its kind of any county in the country, and records of the Sichuan Railway Protection Movement of 1911 archives are considered especially valuable. Select official documents of the former province of Xikang during the Republican period (1930s–1940s) are also available. (Xikang was merged with Sichuan following the founding of the PRC in 1949.) Also available are a limited collection of Western language files, including 136 files of documents of the French Consulate in Chengdu from 1908 to 1949 and the 872 files of English language documents of the Chongqing office of the Chinese Maritime Customs Service, 1891–1949. Sichuan Provincial Archives has published a very comprehensive 759 page guide to its collection. The majority of visitors are professors and graduate students from Sichuan. Some of the archival documents have been locally scanned and it may take several years more to digitize all the materials. It was agreed that to preserve the archives, digitization was the answer and they were moving in that direction. The Archives hoped to integrate all the archives into a national system. There was a card catalog which was organized by topics.

Religious Archives

A special repository which should be mentioned is **The Archives on the History of Christianity in China** at the Hong Kong Baptist University Library, Hong Kong.

The Archives was established in 1996 to serve as a research center in Asia for scholars. The collection covers both primary and secondary English and Chinese language source materials concerning Chinese Christians, missionaries stationed in China, church history, and other materials pertaining to the history of Christianity in China. There are over 3,400 volumes of correspondences, diaries, manuscripts, monographs, and serials, as well as over 31,000 microform items. The extensive microform collection was a result of the generosity of a 3-year \$120,000 grant from the Henry Luce Foundation. There are hundreds of biographies and memoirs in the Archives. For the period between 1950 and 1970 there were newspaper clippings on the history and development of religions in China. In addition, a digitization project on *China through the Eyes of CIM (China Inland Mission) Missionaries* database was completed. The database includes 225 lantern slide and glass plate negative images of portraits, landscapes, scenery, and architecture in China as well as photos documenting the socioeconomic activities of the Chinese from the 1900s to the 1930s.^[24]

China's Archival Education

Since 1949 Chinese archival education has been regulated by the state. There are archival training programs in secondary schools, colleges, postgraduate institutions, as well as in-service training, adult education, correspondence courses, and television courses. In 1992 there were approximately three dozen Chinese institutions of higher learning offering archival education courses, with a full-time faculty of 500 and over 7000 students enrolled. Sixty

secondary schools offered archival service training and in 1992 there was a total enrolment of more than 1000 students at that level. In-service training from the provincial level to the Archival Administrators' Education Centre in Beijing offers courses to thousands of mid-level and higher-level archivists. The SAB, the Ministry of Education, and the Chinese Archives Society were all involved in archival education.

China People's University

At the China People's University (Renmin Daxue), the Archives College, a teaching and research center, was established in November 1952; since then Renmin has been the leader in China's archival education. Located in the western suburbs of Beijing, the College was designed to train professionals engaged in archival work. It also trained faculty to teach archival science. The Archives College has a faculty of 54, including 30 professors and associate professors. The 4-year undergraduate curriculum offers majors in three areas: archival science, administration of scientific and technical work, and archival preservation. The 3-year graduate studies program offers concentrations in archival science and in the history of Chinese archival systems. A 2-year certificate program of specialized education is awarded to majors in archival science and in document administration. Not until 1994 did the college develop a doctoral program in historical document science, including archival science. In the 40 year period from 1952 to 1992, a total 4489 graduate students completed their archival training, and many of these alumni have become well-known scholars and leaders in the archival profession. Students from other countries have studied at People's University and professional archivists and educators from Russia, Canada, and the United States have taught there.

Professional Associations

Founded in 1981, the CAA (*Zhongguo Dang'an Xuehui*), is a professional organization of Chinese archivists, and is a member of the China Association for Science and Technology. There are branch associations at the provincial level and in local districts. The headquarters of the CAA is in the SAB; its leadership is drawn from the national archival management system and from academics of archival science in universities. The society encourages research in archival preservation, the history of archival management, and archival management education. The CAA has as its goals:

1) to encourage archival academic exchanges with foreign archive institutions, learned societies, and individual archivists; 2) to raise the academic level of members; 3) to spread archival knowledge among members; and 4) to make known Chinese developments and achievements in archive academic research at home and abroad. Examples

of some of the special committees work include: records management, editing and publishing of historical documents, automation, microfilming and reproduction, and conservation. CAA also publishes two professional journals: the bimonthly *Archives Work* and the quarterly *Historic Archives*.^[25]

Chinese archives have undergone major changes, especially since the PRC Archive Law in the 1980s. The Archive Law states that archives should be opened to researchers and to citizens. The range of services as well as the scope and variety of uses for archives has been slowly expanding. Researchers particularly engaged in early twentieth century history from 1900 to 1949 will find increasing opportunities to gain access to the original documents. As China's modernization accelerates, electronic comprehensive cataloging of archival holdings is being explored; it will soon be possible to use online finding aids to locate materials in any Chinese archives that are pertinent to pre-1949 Chinese history.

MUSEUMS AND MUSEOLOGY

Modern Chinese museums appear in a remarkable diversity with regard to size, function, form, and content. The majority of them are public museums administered as facilities of the state, province, municipality, or district, while private museums are operated under different rules. Their focuses frequently evolve around the following subjects: history, religion, ethnicity, cultural relics, science and technology, arts and crafts, famous people, sports, and paleontology and archaeology. They encompass most ordinary types ranging from aviation to natural history museums, in addition to unique ones such as those on modern Chinese revolutionary history, traditional Chinese medicine, historical salt /mining industry, ancient astronomical instruments, and silk and tea industries.^[26]

Since the past two decades, China has been rebuilding and expanding existing museums, as well as updating exhibition facilities and constructing new ones. While only less than 30 museums were visible in major cities when PRC came into existence in 1949, 480 museums were recorded in the 1950s, and a rapid flourishing of museums concurrent with the rise of market-based economy was observed in the last decade of the twentieth century. The number reached 1357 in 1999, and a total of 1722 public museums of all varieties were operating in 2008.^[27] The list is estimated to have more than 2300 when nongovernmental museums are also being included.^[28] It appears that only a mere 300 are related to subjects in scientific studies, and most were established after the turn of the twenty-first century.^[29]

Of all the Chinese museums, approximately 120 currently located in the capital city constitute the highest concentration in a single city. Among them are some of the most popular ones scattering along the western section

of the east–west oriented Chang'an Street. The Palace Museum in the Forbidden City, now commonly known as the “former Palace,” as well as its 1,000,000 pieces of artifacts in the collection, represents a complete ancient palatial complex dating back to 1420. The walled complex of 720,000 m² was the seat of a succession of Ming and Qing imperial houses until the last emperor Pu Yi was expelled in 1924.^[30] The Palace Museum in the Forbidden City along with the Shenyang Palace Museum in Liaoning Province^[31,32] are important sources for understanding the life and history of the Qing imperial house.

Near the Palace Museum of Beijing is the Chinese National Museum in a structure composed of two separate units: the Museum of the Chinese Revolution and the Museum of Chinese History. The former is designed to interpret the modern history of China with a focus on the Communist Party. The latter had been expanded from its predecessor, the Beijing History Museum originally built in 1912. The items in the collection include the fossils of Chinese *homo erectus*, Neolithic potteries, bronzes and ceramic wares from dynastic periods, in addition to a rare bronze human sculpture marked with acupuncture points.^[33] Besides the Palace Museum in the Forbidden City, the Museum of Chinese History with its 300,000 items in its collection has only two rivals in terms of the size of their collections: the Tianjin Natural History Museum of Hebei Province and the Nanjing Museum (formerly National Central Museum) of Jiangsu Province.^[34]

The new version of the Beijing Capital Museum farther west inaugurated in 2006 is regarded as one of China's leading museums to exemplify elements of a modernized institution. The architectural complex of outstanding design is built to accommodate a maximum of 2000 visitors for exhibitions, educational activities, and conferences requiring multilanguage interpretation services. In the galleries, special exhibitions such as “Ancient Calligraphy,” “Stories of the Capital City,” and “Treasures of Peking Opera” complement permanent installations to recount the history and cultural aspects of Beijing city, with topics ranging from its Paleolithic beginnings to the recent past. These are designed to reflect the goal of the museum that stresses integration of collection, exhibition, restoration, and research into education.^[35]

Apart from museums dedicated mainly to China's past, the China Science & Technology Museum located near the northern section of the 3rd Ring Road is a national institution to demonstrate that China is abreast with rest of the world in an increasingly globalizing world of technology. Its programs are carried out through permanent and short-term exhibitions, onsite activities, and shows at a domed-shaped Astro-vision film theater, which is one of the largest worldwide. In the museum complex constructed in 1988 and expanded in 2000, exhibits of different fields of modern science introduce the basics of mechanics, electromagnetism, heat, acoustics, optics, air and space, energy, transportation, mechanics, material

science, environmental science, nuclear technology, and information technology. The return capsule of Shenzhou No. 1 spaceship and its parachute are also displayed to explain the science of astronautics. Others are presentations on ancient Chinese technology (astronomy, compass, gunpowder, bronze metallurgy, papermaking, and printing) to document China's scientific inventiveness and technological preeminence in the past. Prior to 1999, the museum was one of the few in the country to have encapsulated training-based education programs and experiment-based displays.^[36]

The new building of the Chinese Science and Technology Museum located in the Olympic Green just north of the National Stadium (nicknamed “Bird Nest”) is built with government investment. As one of the auxiliary facilities of the 2008 Olympics, this new facility has debuted with an exhibit on scientific and technical innovations of ancient China, and is anticipated to be in full operation during 2009. It will be a milestone to follow two other supersized hands-on interactive museums: Shanghai Science and Technology Museum (2001) and Guangdong Science and Technology Museum (2008). Concurrent with the opening of the Summer Olympics is the inauguration of the Beijing Jingcheng Olympic Education Museum in the northeastern section of the city, sponsored by a private educational organization in commemoration of the 2008 game.^[37]

Among the 30 museums in Beijing showcasing materials associated with scientific studies, the Beijing Museum of Natural History in an area south of the Tiananmen Square is one of the old national museums founded in the 1960s. Its reputation is built upon rare specimens displayed in four specialized sections (paleontology, zoology, botany, and anthropology), domestic and foreign traveling exhibits, award-winning museum projects, and research projects collaborated with international teams, museum publications, and its museum association.

The museums in the capital city encompass the oldest and the newest aspects of human existence. The Beijing Museum of World Art at the Millennium Monument is the first in China to have focused on diverse artistic aspects known in world history and modern societies. The museum emerged onto the international art map in 2002 when an electronic display entitled “Salvador Dali: A Journey Into Fantasy” was held in its digital gallery. Its exhibitions cover a wide spectrum of subjects and media pertaining to a convergence of art and technology, including different forms of digital imageries facilitated with links to the World Wide Web.^[38] Aside from having become a window through which art and technology communicate in a contemporary global setting, the Beijing World Art Museum also has pioneered in incorporating enterprise-style management into its operation system, which appears atypical at traditional Chinese museums.^[39]

Less well known in the city is the Arthur M. Sackler Museum of Art and Archaeology on the campus of Peking

University in northwestern Beijing, an institution characterized by its modern concepts in artifact display and conservation. As an affiliate of the Department of the Archaeology at a university similar to its peers at the Northwest University, Sichuan University, and Shandong University, its hands-on projects in laboratories and archaeological sites are major educational resources for scholarly research and a training ground for new-generation archaeologists and museologists. The Sackler Museum of Beijing opened in 1992 and is accessible to general public.^[40]

Away from the capital city are local-based museums of different nature, administered by state, provincial, municipal, regional, or private organizations. One of the prominent museums in the south is the Nanjing Museum (formerly National Central Museum) of Jiangsu Province. In 1933, it was conceived as a national institute and the prototype of modernized Chinese museums when Mr. Tsai Yuan-Pei (Cai Yuanpei), the head of the national academy, proposed to construct a public museum complex to address distinct themes pertaining to culture, technology, and natural science. The museum was eventually established as an organization to exclusively house collections of works of art and artifacts acquired through purchase, archaeological excavation, and exchange, as well as to engage in research and conservation of these materials. Incorporated into its large artifact collections are also important archaeological finds taken from sites in nearby regions, including the Neolithic jades from Liangzhu cultural area. The Nanjing museum is famous for having actively published periodicals and research materials, conducted educational programs and archaeological excavations, and hosted special exhibitions from foreign collections in addition to organizing exhibitions to travel internationally.^[41] The museum also serves as the headquarter of regional cultural organizations, including the Association of Jiangsu, Institute of Archaeology of Jiangsu, and the Association of Folk Culture of Jiangsu.^[42]

An additional sophisticated museum in the same province is the internationally renowned Shanghai Museum. It is the base for a collection of 120,000 pieces of ancient Chinese art works and archaeological materials. Displayed in separate exhibition halls are some of the finest and rare specimens ever created in Chinese history. Aiming to conserve, display, and promote aspects of cultural diversity,^[43] the essentials of a modernized museum can be discerned in its featured exhibitions and research facilities, educational, visiting, and exchange programs, along with eleven galleries, three special temporary exhibition halls, its superb conservation department, library, gift shop, coffee shop, cafeteria, and a multimedia meeting room equipped with translation services. The innovated museum building of 1997, which symbolizes traditional Chinese understanding of the universe: the circular heaven above and the square earth beneath, attests to the changing

taste from the norm of old socialistic aesthetics.^[44] The museum operates with 85% government funding in conjunction with donations from private sectors.^[45]

Rich collections of historical relics and archaeological materials also have become highlights at the major provincial or district museums, such as the Shaanxi Historical Museum, Hubei Provincial Museum, Zhejiang provincial Museum, Yunnan Provincial Museum, and the Ordos Museum in Inner Mongolia. Nevertheless, one of the most unique forms of museums in China are those with exhibition halls constructed at archaeological sites that have been designated as protected cultural areas. Among them, the Museum of Banpo Neolithic Site in Xi'an City, the Terracotta Warriors' Museum of the First Emperor of Qin in Shaanxi Province, Dunhuang Cave Museum in Gansu Province, the Sanxingdui and Jinsha Museums in Sichuan Province, and the Yinxu Museum in Henan province rank among the top tourist attractions. Many of these have been incorporated into the UNESCO list of World Cultural Heritage sites.

In addition to exhibitions, activities such as research projects, seminars, and conferences also are parts of the fabric of Chinese museums. The results of these works are made available to the public through museum publications. The Chinese museum literature shows a long list of research reports and monographs, along with preeminent professional journals such as "Party History Research Data (*Dangshi Yenjiu Ziliao*)," "Journal of National Museum of Chinese History (*Zhongguo Lishi Wenwu*)," and "Palace Museum Journal (*Gugong Bowuyuan Yuankan*)." Others are popular magazines edited by professionals at the Geological Museum of China, Beijing Planetarium, and the China Science and Technology Museum, to name a few. They enjoy equal fame with "The Great Nature (*Daziran*)" of the Beijing Museum of Natural History, a favorite magazine for young readers nationwide. The illustrated monthly "The Forbidden City (*Zijincheng*)" of the Palace Museum is also one of the popular magazines on cultural history and art.

Additional museum periodicals with sections dedicated to museum studies include the "Southeast Culture (*Dongnan Wenhua*)" of the Nanjing Museum and "Relics of Yunnan" (*Yunnan Wenwu*)" of Yunnan Provincial Museum. These in conjunctions with relevant works from non-museum publications, such as "Beijing Relics and Museology (*Beijing Wenbo*)," "Chinese Museums (*Zhongguo Bowuguan*)," "Newsletter of the Chinese Society of Museums (*Zhongguo Bowuguan Tongxun*)," and "News Letter of the Chinese Association of Natural Science Museum (*Zhongguo Ziran Bowuguan Xiehui Tongxun*)" have contributed significantly to the field of museology. The last two belong to the Chinese Society of Museums (*Zhongguo Bowuguan Xuehui*) and the Chinese Association of Natural Science Museums (*Zhongguo Ziran Kexue Bowuguan Xiehui*), respectively, both of which are members of the International Council of

Museums (ICOM). The former also is the largest museum association in the country for organizations related to cultural and historical studies. As an affiliate of the State Administration of Cultural Heritage (*Guojia Wenwuju*), it has been the driving force in organizing workshops and conferences on topics pertaining to museum studies and authentication, collection, and assessment of artifacts. Besides its professional journal “Chinese Museum (*Zongguo Bowuguan*)” and other publications on the subject of museology, “The Annals of China Museum (*Zhongguo Bowuguan Zhi*)” published in 1995 is a compendium of the history of Chinese museums. Currently, the Chinese Society of Museums is collaborating with two other institutions to compile a revised edition of this book. It also will be the organizer of the 22nd General Conference of ICOM, to be held in Shanghai in 2010.

The general outlook of Chinese museums underwent obvious transformation during the past decade due to forces of globalization. The government endorses exchanges of display materials between museums and encourages exhibits of legal nongovernmental collections from domestic and international sources. Frequent blockbuster shows at major museums and corporate-operated exhibition facilities in large cities encourage competition and open-mindedness not known previously, while a free-admission policy introduced at the country’s public museums in 2008 assists in promoting appreciation of China’s national heritage. The negative side of an explosive rise of museums is that shortage of trained museum professionals and training programs in museum studies has become a key issue in the history of twenty-first century Chinese museums.^[46]

Although the exhibition narratives in state-sponsored museums remain to serve the interest of the Party and to dutifully fulfill their roles in the realms of education and social service, changes in the exhibition practices have altered the progression course of Chinese museums. Unique concepts such as virtual museums and “ecomuseum”^[47] have been introduced into the country as novelties; some of the new government funded science museums, frequently mammoth in sizes with multitheaters and being positioned in close proximity to shopping arcades, are morphed into market-based enterprises. In the meantime, private art museums have become profit-generating engines in disguise for artists, collectors, and urban-developers.

CONCLUSION

This study has documented the development of modern librarianship, archives, and museum studies in China. It was not until the nineteenth and twentieth centuries that the transformation of libraries, archives, and museums was initiated, and China began the long process of change; new institutions, values, and techniques were gradually introduced, through self development and foreign

influences. Successive waves of internal and foreign conflicts and influences assisted and hindered cultural developments. Under the PRC, library reforms patterned on Soviet practices were implemented in the 1950s. Following the social upheavals of the Cultural Revolution, Chinese library development resumed, beginning in the early 1980s. In the twenty-first century era of globalization, information and digital techniques have significantly advanced and expanded the role of libraries, archives, and museum services in China. Digital libraries have become an important priority, as well as a significant component in the national information infrastructure. New museums have been built also to showcase China’s ancient and recent past, together with changes in exhibition practices. Archives are opening up to researchers and citizens, and with the expansion of online finding aids, location of archival holdings will be easily found.

In November 2008, the U.S. Institute of Museum and Library Services (IMLS) and the Ministry of Culture of the PRC signed an agreement on the *Partnership for Cultural Exchange* between museum, library, archive, and information services at the LC. The agreement is to share in library and museum services, including education in museums, application of new technologies, and the availability of online information in libraries and museums. A part of the agreement is to establish cultural exchange between American and Chinese librarians. Professor Paula Kaufman, University Librarian and Dean of Libraries at the University of Illinois at Urbana-Champaign, and Dr. Zhan Furui, Director of the NLC and President of the LSC signed the *Think Globally, Act Globally* agreement. This is a 2-year IMLS project with additional support from the LSC. Chinese librarians, library educators, managers of library technology will be introduced to American public library service. U.S. librarians in turn will work with the Chinese librarians to identify Chinese information resources that could be made publicly available through an online portal developed by the team. Training will be in the United States as well as in China. CALA is included as a project partner. In addition IMLS is supporting training for the care of collections—both parties will exchange and disseminate information to promote best practices in the care of collections held in museums, libraries, and archives.^[48]

With new technologies ever developing, it makes it easier to share China’s cultural heritages; but that alone is not enough. It is critical that we must continually engage in dialog and exchange to further build understanding and cooperation among our global counterpart scholars, archivists, librarians, and museum professionals.

ACKNOWLEDGMENTS

I wish to thank Huang Si Ying for her able research assistance and helpful comments from the anonymous

reviewers. I also am appreciative of the assistance of Zhu Qiang, Director of the Peking University Library. In the final section dealing with museum studies in China, I wish to gratefully acknowledge the assistance of Dr. TzeHuey Chiou Peng, Associate Curator of the Spurlock Museum at the University of Illinois, Urbana-Champaign; her knowledge and expertise are invaluable.

APPENDIX

Table A1 Chronology of Major Dates in Chinese History, Libraries, Archives, and Museums

16–11 B.C.	Shang Dynasty—documents carved on tortoise shells and animal bones.
221–206 B.C.	The Qin Dynasty unified China and established China's first central Government.
16 B.C.–1911 A.D.	Imperial libraries served as depositories of national literature and archival documents.
105 A.D.	Cai Lun invented paper.
618–906 A.D.	Tang Dynasty—Printing was invented, beginning with wooden blocks.
960–1279 A.D.	Song Dynasty—Movable types invented; printed books became available in China.
1644–1911	Qing Dynasty (Manchus).
1839–1842	Opium War, concluded with the signing of the Treaty of Nanjing and China's forced opening to the West.
1840–1926	Public Library Movement.
1850–1864	Taiping Rebellion.
1894–1895	Sino-Japanese War.
1898	Hundred Days Reform.
1899–1900	The Boxer Rebellion.
1909	The Ministry of Education promulgated the first library law in China for public libraries: to preserve Chinese classics, to disseminate knowledge, to provide research facilities, and to collect materials for the public to use freely; also to establish the Metropolitan Library (National Library) and other provincial, county, and district libraries.
1910	Xie Yun-Cang translated from Japanese, <i>Library Education</i> , first book on library science published in China.
1910	Mary Elizabeth Wood founded the Boone Library, to serve as a public library, Wuchang, China.
1911	Overthrow of the Qing Dynasty.
1911 to the Present	Modern Library Movement.
1912	On January 1, the Republic of China was declared with Sun Yat-sen as provincial president. Yuan Shikai, a Manchu general, was elected President.
1916	Legal deposit was established.
1919	May 4th Movement, cultural and intellectual revolution.
1920	Mass Education Movement.

(Continued)

Table A1 Chronology of Major Dates in Chinese History, Libraries, Archives, and Museums (Continued)

1920	First library school, the Boone Library School in Wuchang, China, founded by Mary Elizabeth Wood, together with Shen Zhu Rong and Hu Qing Sheng.
1921	Founding of the Chinese Communist Party.
1922	Chinese National Association for the Advancement of Education founded; a division on Library Education was formed.
1924	China Foundation for the Promotion of Education and Culture was established; administered a portion of Boxer remission indemnity funds to be used for public library developments in China.
1925	The national Library Association of China (<i>Zhongguo Tushuguanh Xuehui</i>) founded.
1925	The Palace Museum, Beijing, founded. China's largest museum. Listed by UNESCO as a World Cultural Heritage Site in 1987.
1925	First Historical Archives of China (Beijing) established—Ming-Qing archives.
1933	Nanjing museum established—a national institute of historical and cultural interests; includes many cultural relics, paintings, calligraphies, and ancient books.
1937	Marco Polo Bridge incident commences Japan's invasion of China.
1945	Japan surrenders. Civil war continues between the Communists and the Nationalist government.
1949	On October 1, Mao Zedong proclaims the founding of the People's Republic of China (PRC).
1950	Treaty of Friendship, Alliance and Mutual Aid between the PRC and the Soviet Union.
1953–1957	China's First Five Year Plan.
1954	State Archives Bureau (<i>Guojia Tanganju</i>) established.
1957	The National Book Coordination Act.
1957	Russian library works translated into Chinese and published as <i>Translations on Library Science</i> .
1958	The Great Leap Forward.
1961	Beginning of the Sino-Soviet Conflict.
1964	China Society for Scientific and Technical Information (CSSTI) founded.
1966–1976	The Cultural Revolution.
1978	Deng Xiaoping launches "opening and reform" policy.
1979	The China Society for Library Science, CSLS (<i>Zhongguo Tushuguan Xuehui</i>) was established in China.
1979	United States and the PRC formally establish diplomatic relations.
1980	Summary Report of Library Work, encouraging governments at all levels to develop libraries and expand their services.
1980	Second Historical Archives (Nanjing) opened—documents relating to the 1912–1949 period.
1981	Chinese Archives Association (<i>Zhongguo Dang'an Xuehui</i>) founded.

(Continued)

Table A1 Chronology of Major Dates in Chinese History, Libraries, Archives, and Museums (*Continued*)

1987	Report Pertaining to the Improvement and Enhancement of Library Work, issued by the Ministry of Culture and other ministries, urging for the coordination of libraries, reform of library management, and adoption of modern technology.
1987	Dedication of the new library building, National Library of China, Beijing.
1991	Journal of Library Science in China (former name Bulletin of the China Society for Library Science). Core leading national journal in library and information science. Jointly sponsored by the China Society for Library Science and the National Library of China, under the auspices of the Ministry of Culture.
1996	Sixty-second International Federation of Library Associations and Institutions (IFLA) General Conference held in Beijing.
1996	China National Knowledge Infrastructure (CNKI). Founded by Tsinghua University and Tongfang Knowledge Network Technology Company; full-text database created to integrate important resources in China, to be disseminated in China and globally.
2005	China Society for Library Science (CSLS) name changed to the Library Society of China.
2008	Opening of the National Digital Library, National Library of China, Beijing.
2008	Signing of the agreement between the Library of Congress and the National Library of China to develop the World Digital Library project.
2008	Olympic Games held in Beijing.
2008	Opening of the Guangdong Science and Technology Museum, Guangzhou, world's largest science and technology museum.

Abstract

Circulation services in public libraries are pivotal to the success of library services. The circulation desk is where library service typically begins and ends for library patrons (users). Patrons come into the library and ask for directions at the circulation desk, to apply for library membership in the form of a library card, and to learn library policy information regarding circulation of materials, computer use, programming confirmations, and more. After receiving reference services from the librarian, patrons go back to the circulation desk to check out materials, pay fines, learn of library programs, and status of requests.

Throughout the history of public libraries in America, circulation areas have been in tune with the technological trends of the day. From due date cards to keypunch operating machines to self-check-out modalities, circulation desks have always been and continue to be the focal point for library patrons to learn the value of the library.

INTRODUCTION

“Circulation services” is the term used to describe many of the most important, yet oftentimes invisible activities of today’s libraries. Circulation services include all activities that are involved in the making of library books, journals, and other materials directly available to the people who need them. Public, school, special, and academic circulation services can be defined as the full cycle of a user borrowing library material and subsequently returning it within a designated time frame. This borrowing cycle has a history alongside the existence of libraries, and even with the advent of technology in library services during these contemporary times, the borrowing cycle continues to be the impetus for library circulation services today.

Circulation in American libraries has been documented since 1856.^[1] Library book circulation over the decades has been relatively stable with an average of 11 books checked out per American public library borrower per year.^[2] With the accessibility of books, films, recordings, videos, CDs, DVDs, software, and audiovisual products in both print and electronic formats, circulation of library materials amongst the reading public has increased (mainly due to electronic borrowing privileges), while physical library visits have decreased.^[2]

It should be taken into account that what was defined as a “public library” or an “academic library” during the nineteenth century may differ from what we define as a public or academic library today. Thus circulation statistics of yesteryear may include public use from libraries that we now consider as school or special libraries. For example, subscription libraries were considered public

libraries during the nineteenth century.^[1] Subscription libraries are considered special libraries today. In the case of academic libraries, when a group of learned men pooled their books together to create a library upon which Yale University was founded, such collaboration attests to what was once perhaps a social library that quickly evolved into an academic library.

Another aspect of circulation services that should be taken into consideration is the circulation of juvenile materials. During the nineteenth century, juvenile materials were not as readily available in public libraries (nor in academic libraries) as they are today. During that time, adult materials counted for a large percentage of public library circulation, whereas today, juvenile borrowing typically counts for a significant proportion of circulation statistics in public libraries. Children’s literature collections are frequently available in academic libraries where the institution offers majors in education, library science, and other related disciplines. Some academic libraries, like University of North Carolina at Chapel Hill and Kent State University, offer extensive specialized collections in picture books. Specialized collections such as these are circulated by adults, as opposed to high circulation rates being attributed to children in public libraries. This increase in juvenile literature circulation correlates with the increase of the publication of children’s literature.

In recent years, there continues to be a rise in the circulation of young adult literature, multicultural materials, and audiovisual mediums such as DVDs, language videos, audiobooks, and electronic books (e-books). This rise in audiovisual circulation speaks of an increase of equitable access to a variety of information in popular

formats, thus libraries can reach broader and more diverse audiences with different learning styles and informational needs. More and more libraries are taking this option to the next level by offering streaming video and e-book services, bypassing the need to download, a feature optimally set for the burgeoning set of smartphone-using patrons. Finally, free online classes (aka MOOCs: Massively Open Online Classes) are being “circulated” through public library catalogs through such vendors as Coursera, Input, Universal Class, Khan Academy, and others.^[3]

Digital technology continues to inspire an evolution in circulation services and practices in libraries of all kinds. Self-service automated systems for users and graphical interfaces for facilitating circulation services by library staffers continue to grow and improve as technological innovations emerge. Staffers and users alike experience new learning opportunities as technology impacts circulation of library materials on-site, in remote storage facilities (physically and in the cloud), and virtually online.

Overall, with staffers continuing to learn new technologies and to employ vital customer service to diverse populations, circulation services remain an important and vital mainstay of library services for all types of libraries.

ETHICS

The privacy of patron library records reaches into the issue of intellectual freedom. As part of the first amendment’s assertion for freedom of expression, libraries hold library records to be confidential because what is checked in and checked out illustrates a patron’s intellectual and personal interests. A library record is like a record of one’s thoughts, ideas, and curiosities. These records must be respected and protected. Staffers are held to the highest form of professional confidentiality and integrity when interacting with and maintaining library borrower records. Even in this age of the US PATRIOT ACT and the Foreign Intelligence Surveillance Act of 1978 Amendments Act of 2008 (FISA), librarians have been uncompromising stalwarts in respecting the privacy of patron records and even insisting that the U.S. Federal Government do so as well.

Librarians’ enforcement of Sections 215 and 505 of the PATRIOT ACT, amendments that have been made to the law to preserve confidentiality of library borrower records echo the professional standards of the American Library Association’s Code of Ethics.^[4] Many academic and public library administrations have also enacted policies, guidelines, and best practices for librarians and circulation staff to follow in the event of legal requests for private patron information.

CIRCULATION DESK

The circulation and reference desks are the two focal service points in a library. At its most basic, the circulation

desk is the location within the building where library users borrow (check-out) materials, renew, and return (check-in) borrowed materials. The circulation desk is mostly staffed by paraprofessionals (library assistants, library technicians, clerks, and, in some cases, volunteers) as opposed to the reference desk which is mostly staffed by librarians, assistant librarians, and library trainees.

As the initial entry and exit point for library users, the circulation desk serves three primary functions: 1) facilitating user information needs, 2) collecting and filtering library materials, and 3) facilitating user-centric information needs such as processing library card applications, library card renewals, paying fines, and handling borrowing privileges. Another set of functions involves the collections. As borrowed material is returned, or as material used in-house is gathered up, the circulation desk serves as a collection point and a filtering point. It is at the circulation desk that any damaged or mutilated returned items, or any item returned with missing parts (i.e., cases, discs, and pamphlets that make up many audiovisual items), will be first noticed. From the circulation desk, items are then sent on to the appropriate area depending on whether the items are to be re-shelved or sent to the processing room for repair or de-accessioning if the item is damaged.

A third set of functions served at the circulation desk rises from the fact that the circulation desk is usually the first point for anyone entering a library and is the last point before leaving the library. Because of this important position, the circulation desk itself should be clean, clear of clutter, and inviting. The circulation desk staff, then, is responsible for greeting people, being inviting, and having knowledge of the library’s policies and procedures as well as a basic knowledge of locations of materials (sometimes known as simple reference). Upon entering the library, users, in many cases, will come to the circulation desk first and then be directed further into the library to confer with the librarian(s). In short, the circulation desk is the touchstone for user experience in most libraries.

The circulation desk is a locus of technology in many libraries. Check-in and check-out terminals, cash registers, camera equipment for library cards that carry photos; sometimes photocopying machines, faxes, and public telephones are found at or near the circulation desk and, in any case, tend to be under the purview of the circulation desk staff.

Libraries may designate various names to the circulation desk such as “Information Desk,” or “Information.” Libraries will typically have dominant signage that indicates the location of the circulation desk as the initial point of contact for library users.

The circulation desk may be the most important location in a library, at the very least equal in importance to the reference desk. Whereas the reference desk is where users learn and access the content of the library, the circulation desk is the contact point between the library, as a whole, and the wider community outside the library.

KINDS OF CIRCULATION

Circulation is the movement of library materials usually from within the building out into the service community of a library and back again. Library users are the prime catalysts of this movement; it is the users' information wants and needs that cause books and materials to go out of the library, and thus the user is responsible for returning the material. This output–input process is commonly known as checkout (also known as “charge” and “borrow”) and check-in (also called “discharge” and “return”). This culminates the most basic understanding of what it means to circulate library materials.

Typically, not all items and materials in a library are allowed to circulate. Materials that do not circulate are typically referred to as the reference collection or non-circulating collection. Reference materials can be checked out in special circumstances based on the borrower's needs and at the librarian's discretion. Reference materials typically are borrowed overnight, two days, sometimes as long as a week, in public libraries. In academic libraries, reference materials can be checked out for an extended amount of time for faculty and/or course use.

Circulation can take many forms, depending on the kind of library, the service community, how technologically advanced the library's systems are, and the size of the library's circulating collection. Aside from charging and discharging materials, if a borrower returns material past the due date, a fine is typically incurred on a daily basis until the material is returned. In public library systems, this fining schedule will often have a capitalizing limit whereas after a certain amount of fines are accrued, the entire cost of the material is charged to the patron instead. In this situation, upon return of the late material a patron either returns the material and pays the maximum capped fine or does not return the material (the item is lost) and instead pays the cost of the material for purposes of item replacement.

If a patron's borrower record illustrates a pattern of lost and/or missing materials along with unpaid fines, his/her record can be blocked from further circulation activities until the record is expunged either by payment, return of materials, or some other arrangement coordinated with the library administration. In school and academic libraries, lost library item costs can be added to a student's financial record and can block administrative services such as the release of grades and transcripts. Similar sanctions can occur in special libraries and archives.

At a basic level, in most libraries users may borrow up to a set limit of items from the circulating collections—fiction and nonfiction books, audiovisual material including DVDs, videos and audiobooks, and magazines (in print and electronic formats), and can hold items for a set period of time (two weeks, four weeks, seven days, overnight, etc.) before returning them. These set limits and time periods, known as borrowing privileges, differ from

library to library. If a library has a small collection, the maximum number of items that can be borrowed might be less than in a library with a larger collection. By the same token, the time period a person may place a request on an item (also known as putting an item “on hold”) may be shorter, creating a quicker turnaround time ensuring the item will be available more often. Items that are in high demand may have shorter due dates for the same reason. Multimedia items, such as DVDs, videos, music CDs, gaming, and software discs, might have shorter due dates based on the premise that these items do not take as long to listen to, or view, or use as the time it may take to read a book. To meet the demand of largely requested titles or items, librarians may keep multiple copies of an item “on reserve” for patron use in-house. Reserves are commonly offered in academic libraries to accommodate instructors who want textbooks or other materials available for class review.

Another kind of circulation involving technology involves the use of a library's website and downloadable material. In this kind of circulation, the library user enters his/her library card number (or some other acceptable code) and downloads a digital file containing an entire book, music, or video, onto his/her computer, tablet, or handheld device. Once downloaded, the file can be read or viewed by the user. After the established due date is reached, libraries commonly enact digital rights management to cue the file to automatically disappear from the user's library account. Libraries comply with legalities associated with digital rights management (DRM) to enact the ethical return of digital data and files to the library collection. Digital rights management technologies serve to control copyright protection so that users cannot copy, sell, or inappropriately possess library materials. It is DRM technology that is in play when electronic library materials are “returned” (via disappearance in user's account) to the library's holdings.

The option to stream books, music, and video is beginning to appear on many libraries' websites. As technology improves, vendors marketing products proliferate, and the availability of platforms (smartphones, advanced e-readers, tablets, laptops, PCs) to access these features spreads, patrons are able to bypass the standard check-out/check-in paradigm.^[5] The nature of streaming is immediate and temporary (while the patron is actively using the item), so it does not resemble the typical circulation transaction. Still, accessing these services requires a library card number to be entered for the transaction to occur and the patron's library card needs to be in good standing regarding the amount of overdue fines, late books, or lost item fees exactly as in traditional circulation transactions involving print items. Vendors such as Overdrive, Freegal, Hoopla, Indieflx, Zinio, and Smithsonian Global Sound for Libraries are just some examples of companies offering streaming features on library websites.

As streaming technology and accessibility improves, libraries are in a unique position to consider content creation as another service to the community. One of the strengths of libraries is the ability to collect and preserve the history and culture of a community. The library collects knowledge of local relevance to the community and, in many cases, is the only source for such information.^[6] How this local content creation is circulated, and what impact it will have on circulation overall, will pose an interesting question for library administration to consider.

The kind of community the library serves can have an effect on circulation. A special library in a law firm or business or an academic library catering to a specific population might have a very different circulation policy than a public library serving a broad and diverse geographic community. A library with more funding, and thus able to buy larger collections and replace items more easily may have more generous borrowing privileges than a library with less funding.

In certain special libraries, because of the population served, circulation, if tracked at all, is considered the number of items taken from the shelves and used in-house as there is no need to take material from the library. In academic libraries, faculty are sometimes given the privilege of checking out materials for extended periods of time, and can place course textbooks and articles on reserve at the circulation desk for student reference use. Nowadays, academic libraries also circulate materials via electronic delivery methods, whereby scholarly articles can be retrieved via interlibrary loan (ILL) and with delivery notices sent by email to students and faculty alike. Such documents are typically delivered in PDF format on the library's secured website, whereupon entering one's login information, a patron can locate and download the requested materials.

The value of circulation, no matter the various kinds it can take in various locations around the world, is a symbol of a library's relevancy and connection to its community.

USER COMMUNITIES

"User community" is a term used to identify any group of library users based on a wide variety of defining terms. Defining terms of a user community can be based on demographics of any kind, whether age, gender, culture, education, profession, socioeconomic status, ethnicity, geographic region, or nationality.

Each user group would have specific information needs that would differ from other user groups, but might not necessarily be completely exclusive or removed from the information needs of other groups. The age levels and reading levels of books; types of circulating collections, reference works, and fiction and nonfiction; the availability and diversity of multimedia; borrowing privileges; and many policies and procedures are dependent upon the user

groups that a library serves. It is the duty and responsibility of administrative librarians, reference librarians, and library staff to be knowledgeable of, sensitive to, and accommodating of the user groups within their service community.

User groups based on age are lapsit, toddler, preschool, school age, high school, teen, home-schooled, young adult, adult, and seniors.

User groups based on culture, nationality, or ethnicity may include immigrants, as well as communities identifying with a specific heritage, language, or history.

User groups based on socioeconomic status could be centered on income levels: urban, suburban, rural communities, home-ownership, homelessness, transience, and migrancy.

User groups based on civic status include immigrants, travelers, court-appointed volunteers, recovery outpatients, patrons of varying mobilities, and prisoners.

User groups based on educational criteria would be concerned with level of schooling, groups working in the field of education, people with college, and graduate degrees.

User groups are unique and specific to their communities, often comprising an admixture of citizens cross-pollinating in multiple groups at one time. Thus all library communities are diverse and must strive to create library collections that can be inviting for users to circulate materials amongst one another with the circulation desk and staff as a friendly interface.

STAFFING

Paraprofessionals are typically the staffers of the circulation desk in public libraries. Paraprofessionals usually possess a high school diploma (or equivalent) as the minimum educational requirement for working at the circulation desk. Paraprofessional staffers go by various titles, but common titles are "Library Assistant" or "Library Technician." Competencies for library assistants include excellent organizational skills, ethical proficiency in mathematical skills, being detail-oriented and technologically savvy, being culturally competent with high-quality customer service skills, and performing entry-level reference services. Through years of experience, library assistants/technicians become very proficient with their knowledge of literature, technology, the community, and library trends. Library assistantship is a common gateway through which paraprofessionals become professional librarians, initially seeking their bachelor's degree in higher education and ultimately earning the master's degree in library science to qualify as a professional librarian.

Paraprofessionals are a vital part of the library staff as they work to control the circulation flow of the library.

Library users check out books at the circulation desk, thus good customer service skills are vital for the successful library assistant. Paraprofessionals also enforce library policy making sure that patrons pay fines as well as ensuring ethical practices with the processing of monies from collected fines and other fees.

Library assistants also work to maintain the order of the library collection. In larger public library systems, paraprofessionals may package and log in new materials for the collection, and they may frequently serve as the primary shelveers of new and circulated materials. A lead paraprofessional may, at times, serve as the librarian in the absence of one. In smaller libraries such as in rural locations, a paraprofessional may be the librarian for his/her location, often running the entire library with a few volunteers.

Paraprofessional training and skill development tends to be an internal function of the library or library system. In larger systems, there is usually a staff training office (most likely within the Human Resources Office) that schedules training sessions, workshops, and professional development opportunities such as webinars, conferences, and guest speakers. In smaller systems or libraries, training may be hands-on, at the circulation desk, during the workday as the new staff member “shadows” the experienced staff members. The efficacy of the latter and financial challenges posed by the former is an ongoing conversation in librarianship.^[7,8]

In best case scenarios, paraprofessionals are encouraged and supported by librarians and library administrators to continue their education through professional development activities. Such activities may include attendance to staff meetings, conferences, technology workshops, and community seminars. Paraprofessionals may also join paraprofessional library divisions within their state library associations. For example, the Nebraska Library Association has a Paraprofessional Section, and the Georgia Library Association has a Paraprofessional Division. Across cultural lines, paraprofessionals are also welcome constituents to ethnic library groups such as REFORMA (The National Association to Promote Library and Information Services to Latinos and the Spanish-Speaking), APALA (Asian Pacific Library Association), and the Black Caucus of the ALA (BCALA).

STACK MANAGEMENT

Stack management, also known as collection maintenance, is that aspect of any library system or unit concerning the care, handling, shelving and storing, and accessibility of library materials, on-site and beyond.

There is a dearth of current discussion on issues relating to stack management in libraries today.^[9] But perusing the written record going back 15 years and further reveals some basic concepts of stack management that remain relevant to this day.

There are five divisions to the process of stacks management also known as collection maintenance.^[10,11] The five divisions are storage and shelving systems (to hold and protect a wide variety of unique materials), housekeeping routines (cleaning stacks and vacuuming books; knowing and reacting to specific material needs and environmental conditions), general care and handling practices (broad set of activities that protect materials that are handled, proper techniques to handling materials and how material should be shelved and stored), care and handling routines in processing (proper techniques in handling items throughout the journey of processing, borrowing, charging, and storing the item repeatedly, during its life in the library), and collection improvement activities (noting when and how to best screen and identify damaged and problematic materials within the circulation cycle and the processing stream). These divisions hold for libraries across the profession whether public, academic, or special.

The primary responsibility for maintaining a robust stacks management program and implementing collection maintenance activities rests primarily with circulation staff. In many situations, responsibility during acquisition, cataloging, shelf preparation, and binding will lie with technical processing staff. Cleaning and buildings staff might well play a role in housekeeping functions or when the literal nuts and bolts of the shelving systems to be used are discussed and established. And, as in so many systems or programs, the role of library administration is to ensure that clear, firm policies are established, disseminated, and accessible and that priorities are set, known, and supported.^[12]

In recent years, stack management has evolved to include the relocation of print collections to digital format and/or to off-site locations. Print collections are becoming smaller in many libraries due to the changing focus of the library from a collection storage facility to a more inclusive space for community interaction and exchange.^[13] With the shift of the foci on libraries from artifacts to community building, some libraries blend collection maintenance and stack management routines into one circulation department. Large systems such as university libraries may opt to separate the stacks management functions from the circulation department to promote better efficiencies in getting the material in question back to the shelves and made available in a more timely fashion.^[14] Many large public library systems also have a separate stacks section removed from the functions of the circulation department while at the same time allowing a blending of both routines on the branch or unit level as needed (author's observation, 2014).

The digital age has also delivered new formats for books that affect the circulation and management of library stacks and collections. E-books (as well as e-magazines and e-audiobooks) can now be checked out and loaned and renewed online via in-house electronic circulation systems, mobile applications, and library websites with digital

platforms such as Overdrive, OneClickdigital, and Bookshare, without library patrons needing to be physically at a library circulation desk.^[15,16] Facilitating circulation of e-books and managing their circulation records often falls within the professional purview of library circulation managers and clerks.

Earlier challenges for making e-books accessible from the publisher to the reader have been progressively met. With e-book access having progressed due to the work of librarians, stakeholders, and the ALA Digital Content Working Group (DCWG), the challenge now is to make e-book lending a satisfactory user experience for library patrons by incorporating emerging trends such as e-book subscription models, self-published authors, and the online availability of e-book retailers such as Amazon and Netflix. All these trends shape reader expectations requiring the knowledge base of librarians and circulation staff to constantly change to meet user information needs.^[17]

With the increased availability of print, audiovisual, and electronic resources on the Internet and through databases, and the trend toward virtual reference, the need for physical stacks and collections is changing dramatically with an increase in library collections being moved to digital records and/or remote storage locations in order to afford more physical space for human interaction within library walls. Remote services and management of customer knowledge and patron usage patterns continue to grow in importance in this online, mobile, virtual world era. The policies and procedures, the theories and applications, for the future of stack management and collection maintenance are even now being discussed, formulated, and written.^[18]

TECHNOLOGY

Since the formal professionalization of librarianship in 1876, technology in libraries has continuously evolved to employ the latest technology of the times. During the nineteenth century, books were checked out using a hand-written ledger system, where librarians would write down a user's due date as a line item action for each title borrowed. Technology quickly evolved where systems for circulation services were comprised of permanent card systems and metal plate systems by the early twentieth century.

With the card system, a permanent identifying card was generated for every book acquired for the library collection. The card was kept in the book, and then removed from the book when borrowed. This system is still employed today in some rural public libraries, school libraries, and academic libraries for in-house reserve materials. The metal plate system was considered an improvement over the card system because the user's information was permanently embossed on a metal plate, allowing for a decrease in error when recording borrower information. With the plate

system library staffers were also able to automatically set due dates on library cards.

In the late 1940s, early efforts at using new data processing techniques revolved around the idea of batch processing using key punch cards. These new systems were fast and dependable, could produce overdue notices on demand, and did not require any filing. Some of the drawbacks to the batch processing system were lack of a user database, and lack of inventory control of collections. Most batching processes took hours to complete, so would occur overnight in many public and academic library systems. The batch would process information about materials checked out, but not record information about materials still on the shelves. This made the quality of expanded circulation services, such as book reserves and interlibrary loan, cumbersome and unreliable, as books were hard to locate in the library, since there was no consistent inventory record. Not offering much improvement on older circulation technologies like the ledger and metal plate systems (in terms of keeping record of whole collection management schemes), batch processing was eventually superseded by computer online systems during the later half of the twentieth century.

Subsequently by the 1970s, circulation services in both public and academic library systems were incorporating bar code readers, scanners, and laser technology, to process check-ins, checkouts, holds, reserves, and interlibrary loan requests, as well as modernizing inventory storage records into the form of digitized data. Radio-frequency identification methods (RFID) allow for library users to manage their own check-out processes with the use of wireless technology that scans a microchip embedded in a user's library card and also tagged within the library material to be borrowed. Self check-out machines read the information on the library card and connect that information with the borrowed material via a radio signal, creating a transaction record that is logged in the library catalog. RFID technology can also assist library circulation staff with the book handling process of returned items with systems that automatically read returned items from the book drop, processes the check-in procedure on a user's library record and sends the library item to the appropriate bin for re-shelving.^[18] Along with ILS, RFID, and graphics-oriented interfaces for managing borrowing processes at the circulation desk, technology continues to impact circulation services by incorporating self-service automated developments for public and academic libraries.

Newer advances in technology appearing at the circulation desk include cash registers networked to the check-in and check-out terminals and RFID terminals that allow library users to check out material themselves by placing the item on a scanning plate or waving a light wand over the item's barcode. This produces a receipt with information on which items were checked out, how many items were checked out, and due dates. It is the responsibility in most libraries for the circulation desk staff to

assist library users with this new technology and to come to the aid of the user when technical glitches occur.

In more recent years, innovations in web development allow library users to access their library accounts via the Internet to renew materials, manage requests, and pay fines. Users can now access their library accounts from library websites via their personal computer, laptop, tablet, or cell phone. Library users can also borrow technologies to use in the library and to check out to use at home. Some technologies that are now circulated in libraries include computer laptops, headphones, calculators, voice recorders, CDs, DVDS, gaming items, and digital cameras.

Citation Analysis

Howard D. White

College of Computing and Informatics, Drexel University, Philadelphia, PA, U.S.A.

Abstract

References *from* publications are at the same time citations *to* other publications. This entry introduces some of the practical uses of citation data in science and scholarship. At the individual level, citations identify and permit the retrieval of specific editions of works while also suggesting their subject matter, authority, and age. Through citation indexes, retrievals may include not only the earlier items referred to by a given work but also the later items that cite that given work in turn. Counts of citations received over time, and measures derived from them, reveal the varying impacts of works, authors, journals, organizations, and countries. This has obvious implications for the evaluation of, e.g., library collections, academics, research teams, and science policies. When treated as linkages between pairs of publications, references and citations reveal intellectual ties. Several kinds of links have been defined, such as cocitation, bibliographic coupling, and intercitation. In the aggregate, these links form networks that compactly suggest the intellectual histories of research specialties and disciplines, especially when the networks are visualized through mapping software. Citation analysis is not without critics, who have long pointed out imperfections in the data or in analytical techniques. However, the criticisms have generally been met by strong counterarguments from proponents.

INTRODUCTION

In specialties with literatures, citations link earlier and later work. They denote unique writings and connote concepts associated with those writings. They reveal the citer's intellectual sources in preparing a new text and enable readers to retrieve them. In Derek Price's useful distinction,^[1] further discussed in Wouters,^[2] a work's *references*, made in its footnotes or endnotes, are "outgoing mail" that it sends to older works. A work's *citations*, in contrast, are "incoming mail" that it receives from newer works. It is common, however, to refer to both as "citations" and let the context indicate whether they are incoming or outgoing.

Such linkages may be interesting even at the level of individual documents. In general, however, more interesting patterns emerge when citations from many sources are analyzed in the aggregate. Then one can learn such things as a field's most highly cited authors or works (intellectual bestsellers, so to speak), the primary influences on a particular author's body of writings, and authors or works that are repeatedly cited together over time, indicating that in the eyes of citers they are highly related. Researchers use the latter sort of information to investigate the intellectual structure of learned specialties and disciplines. Citation analysis along these lines is a major part of bibliometrics, the subdiscipline of library and information science (L&IS) devoted to the quantitative study of literatures.^[3] It is also the form of L&IS research most widely adopted by other fields—in part because citation analysts have long used visualization techniques to make relationships in their data easier to grasp.^[4–6]

Entries complementing the present one are McVeigh's "Citation Indexing and the Web of Science" (p. XXXX), Bar-Ilan's "Informetrics" (p. XXXX), and Brooks' "Citer Motivations" (p. XXXX). This entry focuses on research in which citation counts come into play as raw data. It draws examples from the Web of Science (WoS), because of that system's historical importance in revealing the possibilities and problems of citation-based bibliometrics, especially in the journal-oriented sciences. Examples are also drawn from the WoS citation databases on the Dialog Classic retrieval system, because its software could quickly retrieve and display bibliometric data in useful formats not seen elsewhere. Dialog was retired by ProQuest, its parent company, in 2013.

The WoS continues to be a major resource, but after decades of being the only widely regarded source of citation data, it now has formidable competition from Elsevier's Scopus, Google Scholar (GS), and Microsoft Academic. WoS and Scopus can themselves generate reports for subscribers with routine bibliometric questions, while a free system called Publish or Perish^[7] does the same for GS and Microsoft Academic. Nevertheless, many studies can be carried out only by downloading records from these services and analyzing or visualizing them with external software, such as the Sci2 toolset,^[8] CiteSpace,^[9] or VOSviewer.^[10]

Specific citation analyses are matters of practical concern, since they are often published as evidence for knowledge claims and are sometimes used in making consequential decisions. They have been brought to bear on national scientific and technical policies, evaluations of

organizations to determine funding, and academic tenure and promotion cases. They are used to map literatures, reveal networks of citers and citees, and assess the impacts of organizations, authors, journals, and individual works. They also have uses in library collection evaluation. Historically, citation data have come largely from journal articles, but other document types, such as books, conference papers, dissertations, and patents, are increasingly mined as well.

Bibliometrically speaking, however, publications are no longer judged solely by the citations they have received. Shared document repositories (e.g., arXiv), reference managers (e.g., Mendeley), and social media (e.g., Twitter) have led to alternative measures, which are called “altmetrics,” to differentiate them from citation-based measures. Altmetrics include counts of the times that publications have been viewed in or downloaded from repositories, bookmarked or shared in reference managers, mentioned or discussed in social media, and, in the case of books, formally reviewed. Another altmetric for books is the number of libraries that hold them in union catalogs such as WorldCat.^[11] Yet none of these measures is likely to replace citation measures; instead, the best of them complement citations as indicators of reader interest in publications and perhaps as raw data for measures of greater complexity.

Many citation analyses require readers to know statistics or mathematics. This entry points to reviews of that research but presents ideas, resources, and analytic techniques at a basic qualitative level. Zhao and Strotmann^[12] covers some of the same topics in greater technical detail.

CITATIONS AS VERBAL OBJECTS

Both citers and bibliographers briefly describe written works, but they have different aims. Citers adduce other writings in the context of a new work of some creativity—a work for which authorship and a byline are claimed (or claimable). More particularly, they adduce works to support a line of discourse—e.g., as evidence, background, example, or proof. By contrast, when bibliographers make entries in a catalog, bibliography, or abstracting service, they merely register or subject-index works without developing new lines of thought; they are not arguing and documenting a point. Typically, they are not considered authors and do not get bylines.

The distinction between citers and bibliographers bears on collection evaluation. Librarians often evaluate their holdings by checking them against bibliographers’ products, such as *Resources for College Libraries*. However, some librarians draw samples of citers’ products—that is, the works cited in books, articles, and dissertations.^[13] Every item in these checklists has already proved useful in real research, and the librarian can ask, “Could my library have supported that research by providing this

title?” Alternatively, if the sample consists of citations by local authors, the librarian can ask, “Which of the titles in my collection does the home team most heavily use?”

Citations show the *editions* of the works the citer referred to—the copies of a text made from a particular master. The routine fields of conventional citations (e.g., author, title, journal, date, and pagination) function jointly to identify editions. The author and title by themselves name a work but not the specific version of the work’s text—the edition—that was consulted. While many published works exist in only one edition, there is a permanent possibility of more than one, and since they may vary in quality (to the point of having different evidentiary or aesthetic value), we want a means of telling different texts of the same work apart, even if we never actually retrieve more than one. Conventional citations have just enough data to disambiguate in this fashion. They lead to “known item” retrievals in bibliographic databases and library catalogs, which typically use editions as their units of analysis.

More abstractly, citations represent written works as to *authority*, *age*, *subject matter*, and *form of knowledge*. The last is the author’s orientation toward the subject matter—e.g., scientific, technical, historical, or personal.^[14] *Authority* is rendered, first, by naming whoever is responsible for the content of the work, and, second, by naming whoever released that particular version of it to the world—respectively, the author(s) and the publisher, both of whom exercise editorial quality control over content. *Age* is implied by publication date. *Subject* and *form of knowledge* are rendered through the content and style of the title (and possibly subtitle). They may also be rendered by a name connected with the publisher—e.g., the title of the journal or monographic series in which the work appears.

The four kinds of information are not always present. This may result from citers’ carelessness or from defects in the works themselves, as when they lack a publication date or have unrevealing titles. Less often, it results from convention, such as the journal *Science*’s policy of omitting titles from citations to save space. Ideally, however, citations communicate all four, and the ideal is frequently realized in practice.

At the level of a self-contained citation, the four are simply qualitative variables whose values have both explicit and implicit meanings. Explicit meanings are those that any educated reader might receive without special knowledge of the field in which the citation is made. Implicit meanings are those accessible to a field’s insiders through their knowledge of reputations, technical vocabulary, rhetorical styles, and the like. To insiders, a citation can connote subject matter not explicit in the title of the work. Such connotations are part of a field’s intellectual history, as doctoral students come to know it. In information science, for example, one might happen on this citation:

Bradford, S. C. (1934). Sources of information on specific subjects. *Engineering* 137 (3550): 85–86.

From the opaque title, outsiders could not guess that this paper is the origin of Bradford's law of scattering, a pillar of modern bibliometrics. Bibliometricians, on the other hand, might be surprised that the paper is cited at all, since the findings it announced have long been a staple of their thought. As a result, Bradford now goes relatively uncited—a phenomenon the sociologist of science Robert K. Merton termed “obliteration by incorporation.”^[15]

CITATION COUNTS

Talk of relative citedness leads to the notion of citation counts, by which individual citations enter into larger structures of meaning. These structures are the main subject of this entry.

Many published writings are never cited. But many others are drawn into citation networks that preserve information about the history of learned specialties and disciplines. A natural metric in these networks is how frequently authors have cited specific earlier publications. This measure resembles figures on book sales, journal subscriptions, and visits or links to web pages. Like them, it is not a gauge of absolute worth; quality and popularity are not identical.^[16] But when properly used, citation counts are a reasonably valid indicator of reputation in any field, granting that reputations may be increased by controversy.

The counts are metadata that emerge as citations to works accumulate in files. Until 1960, when Eugene Garfield founded the Institute for Scientific Information (ISI) in Philadelphia, there were no such files. *Shepard's Citation Index*, one of Garfield's influences, had enabled the legal profession to trace precedent decisions in court cases since 1873, but *Shepard's* was not regarded as a bibliometric tool. It was only when ISI created the *Science Citation Index*, the *Social Sciences Citation Index*, and the *Arts and Humanities Citation Index* for purposes of document retrieval that analysts could exploit them further as large-scale databases from which to mine statistics on learned literatures.^[17,18] The three previously mentioned ISI tools, which started as printed publications, were moved online as, respectively, Scisearch, Social Scisearch, and Arts and Humanities Search. In 1992, ISI was taken over by a new owner, Thomson Reuters, but the same databases remained available on the Internet, in time marketed jointly as the WoS. At this writing, WoS is offered by a Thomson Reuters spin-off called Clarivate Analytics.

The WoS indexes, described in McVeigh (p. XXX), are designed for “forward citation retrieval”—that is, they allow searchers to look up an earlier work and find the later documents that cite it. (When a later work is used to

find an earlier one, it is called “backward citation retrieval” or “footnote chasing.”) For example, a forward retrieval on Arthur C. Danto's 1964 article *The Artworld* in *Arts and Humanities Search* leads to (among other things) *Farewell to Danto and Goodman*, a 1998 article by Joseph Margolis in the *British Journal of Aesthetics*. All such later articles add up to the earlier work's citation count, or rather to its WoS count—a qualification necessary for two reasons.

First, while the citations in WoS may be *to* works of any sort, they are primarily drawn *from* articles and other types of publications that appear in journals. (Some WoS journal files date from as early as 1900.) WoS now also offers an index to citations from scholarly books (from 2005 on) and another to citations from conference proceedings (from 1990 on), but these require separate subscriptions, and many millions of older works are not covered. Second, WoS bases its coverage of contemporary journals, books, and proceedings in part on their international citedness: publications with citation counts below a threshold are not indexed and cannot contribute to the counts. This citedness policy also tends to favor inclusion of publications in English, the international language of science, and publications from countries dominant in scientific research, e.g., the United States and the United Kingdom.

The most widely used alternatives to WoS are Scopus and GS, both dating from 2004. Scopus, another high-quality subscription service, indexes current materials, especially scientific journals, even more broadly than WoS, but its retrospective coverage at this writing goes back only to 1996. Like WoS, its editorial selection policies determine what it will cover. Also like WoS, it has sought in recent years to improve its indexing of citations from books and proceedings, but again with the same careful selectivity. GS is different: it simply crawls the web, extracts citations from accessible documents regardless of their origin or language, and makes them and their counts available everywhere without charge. GS is increasingly used in serious bibliometrics—for example, in Bensman et al.^[19] Its counts for all sorts of works frequently exceed those in WoS and Scopus,^[20] although in some fields and periods, the latter two have better coverage of the literatures. The policies behind GS data gathering are opaque, and it has been faulted for unreliable data.^[21] But data from the other two major services may require cleaning as well.^[22] Ideally, researchers would combine vetted citations from all of the services (omitting duplicates) to arrive at counts.

MICROLEVEL DATA

The counts of a publication's outgoing references and incoming citations are not the same. For example, Stephen P. Harter's 1992 article “Psychological Relevance and

Information Science” makes *references* to 49 older works (a fixed count). At this writing, it has *citations* from more than 200 newer works in WoS (a changing count). Disciplines vary in the average number of references in their articles and in the average number of citations those articles receive in the years after publication. The latter sets a standard for what a *high* citation rate would be within a discipline, which can be compared in turn with rates in other disciplines. Harter’s article is highly cited in the relatively small field of L&IS, but not in science as a whole.

Table 1 displays what is actually counted. It is a lightly edited bibliographic record from *Arts and Humanities Citation Index* in WoS (in an old-fashioned, space-saving format). It identifies both a 1993 article by Russ Pottle and the publications he cites. His work is thus a “source” article in WoS—that is, a source of the “cited references” in the CR field.

These highly abbreviated CR strings are sufficient to identify works. In Pottle’s case, there are 14, as shown in the NR (number of references) field. Among them are an article by Nina Baym and a book by Ann Douglas, two older works to which Pottle’s is now related. (Either could retrieve Pottle if entered into a Cited Reference search in

WoS.) The citation frequency for any work is obtained by counting the CR strings that identify it in source (SO) publications. For example, occurrences of “Baym N, 1979, PMLA, V94, P909” are counted to get a total for the Baym article, and occurrences of “Douglas A, 1977, *Feminization Am Cult*” are counted to get a total for the Douglas book.

Baym and Douglas are sole authors, but who gets credit for a citation when coauthors are involved? In WoS databases, citations formerly accrued only to the first author, because CR strings identify no one else. Now, coauthors receive credit along with first authors in WoS, just as they do in Scopus. But in downloaded WoS data, one still sees only the CR strings. If one nevertheless identifies all the coauthors, there are two major ways of crediting them: either all get full credit for the citation (their counts all go up by one) or all share equal fractions of credit (e.g., three coauthors get a third of a credit each). Besides affecting authors’ citation records, this choice determines who appears in author maps.^[23–25]

The CR strings themselves can be split into additional variables that are countable across the database. For instance, a count for Herman Melville as a cited author can be obtained from occurrences of “Melville H”; a count for *Publications of the Modern Language Association* as a cited journal by occurrences of “PMLA.” A count for items published in a cited year—say, 1979—is obtained from occurrences of “1979,” as seen in the Baym and Jubak articles in Table 1. Counts of items published in a cited year are used in half-life statistics, described later.

For entities above the level of individual works, such as authors and journals, citation counts may be incremented by how frequently their names occur in the CR strings, or by how many source publications cite them. For example, Melville’s count could go up by *three* because three of his works appear in Pottle’s references, or by *one* because one more source publication—Pottle’s article—cites him. Scopus and WoS display counts of both kinds. GS simply counts citations to individual works and then totals them for authors.

What the citation databases do *not* count are the times a later work refers to an earlier one in its body text—instances of *op.*, *cit.*, and *ibid.*, as it were. Systems do not yet exist for routine analysis of that kind. For example, no matter how many references Margolis may make to “The Artworld” within his text, it is his “Farewell” article that is counted, and so the citation count for “The Artworld” increases only by one. But with greater computer power, frequencies of internal references may in time be captured as an indicator of the importance of works to the citer.^[26]

Fields other than the CR field can be analyzed in WoS records. Given data like those in Table 1, analysts can learn the number of items published by particular authors (AU) and source journals (SO). Institutional affiliations and geographic data for authors can be mined from the “reprint author” (RP) field. (Records for newer articles

give affiliations and geographic data separately in a field tagged C1.) While these data may need extensive cleaning, they are obviously useful in evaluating institutions and countries. One can also get totals of items by language (LA), publication year (PY), and document type (DT). The subject category (SC) field characterizes not individual articles but the journals in which they appear. The SC assigned to the belletristic *Journal of Narrative Technique* in Table 1, for instance, is “Literature.” (Some journals are assigned to more than one subject category.) The full SC scheme in WoS covers most of the sciences, social sciences, and humanities and allows literatures to be broken out by disciplines and subdisciplines.

HOMONYMS AND ALLONYMS

An introduction to citation analysis must warn about the errors caused by homonyms and allonyms. These occur in the strings of text that designate articles, books, journals, authors, organizations, and other entities.^[27] They must be dealt with if the citation counts for any entity are to be accurate. No current software solves the problems entirely; checking is always necessary, and data cleaning may well be.

A *homonym* is a name that is the same for two or more different cited entities. In L&IS, for instance, the string “Wilson P” denotes at least two authors (Patrick Wilson and Pauline Wilson). Homonyms require disambiguation. If the right disambiguator does it—someone who can interpret contextual clues correctly—this may be simple enough. For others, it may be difficult or even impossible. The homonym problem is made worse by the abbreviations in citation databases that nullify disambiguations inherent in natural language. At this writing, WoS has a module for disambiguating abbreviated authors’ names, while Scopus, a newer system, permits retrievals on full names. However, full names, too, can be homonymic.

An *allonym* is one of two or more different names for the same cited entity, such as “Jones KS” and “Sparck Jones K” when both denote the information scientist Karen Sparck Jones, or “Am Lit” and “AL” when both denote the journal *American Literature*.^[27] Allonyms require conflation. This may require as much insider’s knowledge as disambiguating homonyms. To assign accurate counts to certain information scientists, for example, one must know that the name Derek de Solla Price takes many forms in citations, or that Karen Markey is also cited as Karen Drabenstott. If serials have appeared under more than one title, or books in more than one edition, one must decide whether their allonymic citation counts should be conflated or kept separate.

Citers often inadvertently create allonyms by getting names wrong or by misnumbering journal volumes, pages, and years of publication. (These are called “citation variants” in WoS; the broader “allonym” includes both

erroneous and nonerroneous variants.) While such errors may be too singular to affect counts much, inconsistent data entry in all the citation databases can affect counts greatly. WoS has reconciled different versions of the same journal name in the SO field of its records for source articles, but it has not done so in the abbreviated journal names or book titles that appear in the CR strings. Clean sets of older *Journal Citation Reports (JCR)* data are available for comparison studies.^[28,29]

Both homonymic and allonymic problems can beset the same name. For example, the American founder of cocitation analysis, Henry Small, has published under bylines both with and without his middle initial. He is thus cited as both “Small H” and “Small HG.” Since both counts are sizable, these allonyms should be conflated. But other Smalls with the same initials also contribute to the counts, and their homonymic names need to be disambiguated from “the right Small’s.” In the case of Chinese, Japanese, and Korean researchers, name problems are severe.

MEASURES DERIVED FROM COUNTS

Citation counts are the basis of some important summary statistics, such as impact factors for journals and the h-index for authors (see also McVeigh, p. xxxx; Bar-Ilan, p. xxxx). Handbooks from Sweden’s Karolinska Institute^[30,31] describe in detail many of the indexes that can be derived from counts. Further introductions will be found in books by Harzing^[7] and Moed^[32] and in reviews by Mingers and Leydesdorff^[33] and Waltman.^[34] Several indexes are quite controversial; critics challenge their validity for evaluating authors, organizations, and journals.

Journal statistics. As part of WoS, *JCR* provides statistical data like those in Table 2. Such reports are available for journals in the natural and social sciences (not the arts and humanities). They are pegged to individual *JCR* years, e.g., 2013. The “Total Cites” column tells how many citations went in the *JCR* year to all articles published in that journal in a specific year. These numbers have obvious interest for journal editors and also for library serials managers as they decide how to allocate subscription money.

Table 2 ranks by “Journal Impact Factor” some well-known journals in the subject category “Information Science and Library Science” in *JCR* year 2013. The impact factor, which varies from year to year, adjusts journal citation counts by the number of items published, so as to counteract the effects of journal size and age. To compute it, all citations to a journal’s articles in the two years before the *JCR* year are divided by the number of articles the journal published in the same two years. A factor of 1 means that the articles of those two years averaged one citation each. In Table 2, the impact factors for *JCR* year 2013 are based on citations to articles published during 2011 and 2012. At the

Table 2 Ten L&IS journals ranked by impact factors in *JCR* year 2013

Full journal title	Total cites	Journal impact factor	Immediacy index	Cited half-life	Citing half-life
<i>Journal of Informetrics</i>	1152	3.58	0.6	3.2	6.4
<i>Scientometrics</i>	5129	2.274	0.329	6.5	8.1
<i>Journal of the American Society for Information Science and Technology</i>	5125	2.23	0.29	6.6	8.1
<i>Online Information Review</i>	558	1.443	0.042	4.8	8.2
<i>Library & Information Science Research</i>	562	1.384	0.056	7	8.7
<i>College & Research Libraries</i>	528	1.333	0.182	9	7.7
<i>Journal of Information Science</i>	937	1.087	0.117	7.2	8.2
<i>Information Processing & Management</i>	1836	1.069	0.236	8.3	7.8
<i>Journal of Documentation</i>	1046	1.035	0.195	>10.0	9.4
<i>Library Quarterly</i>	291	0.861	0.143	>10.0	>10.0

top, the *Journal of Informetrics* articles averaged almost 3.6 citations each; at the bottom, the *Library Quarterly* articles averaged less than 1 each. (In the hard sciences, one sees much larger impact factors than those of Table 2.)

Researchers know that it is important to publish in good journals, and impact factors are one measure of this. However, such factors do not necessarily indicate the quality of *individual papers* in the journals.^[35] Much of a journal's citation impact depends on a relatively small number of highly cited contributions that the "average" paper may scarcely resemble. Thus, a paper being evaluated (e.g., in a tenure case) should also be judged on other grounds, such as its own citation count and comments from peers.

The "Immediacy Index" is an indicator of how fast-moving a field is—how quickly articles in a journal are cited. To obtain the index, all citations to a journal's articles in the *JCR* year are divided by the number of the articles the journal published in that year. In Table 2, the 2013 immediacy index for *Scientometrics* reflects a faster-moving research field than the one represented by, say, the *Journal of Documentation*.

The "Cited Half-life" of a journal is the median age of the articles in it that are cited in a *JCR* year. Article age is measured from year of publication. In Table 2, half of the articles in the *Journal of Informetrics* that were cited in 2013 were no more than 3.2 yr old. The half-lives of the other journals indicate that citers were drawing on somewhat older materials. Bibliometricians have done considerable work on how publications age (or "obsolesce") in terms of citedness^[36]—a process relatively fast in many sciences and relatively slow in the humanities and the softer social sciences.

Whereas cited half-life pertains to the citations a journal receives, *JCR* also provides data on the references the journal sends out. This is called its "Citing Half-life," and it is the median age of publications that appear in the bibliographies of its articles. Again, contributors to the *Journal of Informetrics* tend to cite newer materials than do contributors to comparable journals.

JCR creates a web page for each journal it covers. The page displays graphs of the journal's half-life trends over

time, its citing and cited relationships with other journals, and the raw counts from which the Table 2 statistics were calculated.

The WoS subject categories define fields in which journals can be compared. One can rank journals by any of the indexes in Table 2 (plus several others) and also alphabetize them by title. It is possible as well to obtain those indexes for aggregates of journals representing entire WoS subject areas. For example, by clicking on the "Categories by Rank" button, one can compare "International Relations" with "Law" in terms of the median impact factors of journals in the two disciplines.

Since 2007, *JCR* has made available two other measures of impact called eigenfactor metrics.^[37] A journal's "Eigenfactor Score" starts with a count of all citations it has received from other journals in the five years preceding the *JCR* year. Then the other journals are weighted by how many citations *they themselves* have received, so that citations from highly cited journals raise the eigenfactor score more than do those from less-cited journals. The second measure, derived from a journal's eigenfactor score, is the "Article Influence Score." It summarizes, in a single value, the influence of all the articles in a journal over the five years since their publication. A score of 1 indicates that the articles have had average influence. Scores above 1 indicate influence above average, as is desirable; scores below 1, the reverse.

Scopus has its own "CiteScore" metrics of journal quality, including the "SCImago Journal Rank" and the "Source Normalized Impact for Paper," as noted in its downloadable guide. GS has also instituted some quality measures for journals under a "Metrics" link and explained how publications qualify for GS indexing under an "Inclusion" link.

Author statistics. Within appropriate domains, authors' raw citation counts always have human interest. They range in order of magnitude from 1 to 10 for obscure scribblers to more than 10,000 for world eminences such as Noam Chomsky and Michel Foucault.

A summary measure for authors that caught on quickly is the "H-Index."^[38] When an author's publications are

ranked high to low by their citedness, h is the lowest number of publications that have received at least that many citations. For example, an h -index of 20 means that a scientist has published 20 papers that have been cited at least 20 times each. The index is intended to capture career achievement by balancing the productivity of authors (their publication counts) with the reception of their work (their citation counts). It should be used to compare authors only within their fields, since disciplines vary in size and citing norms. Errors in counts attributable to homonyms and allonyms must be corrected; otherwise, the h -index can be very inaccurate.

The h -index is now automatically calculated by Scopus, WoS, and (for GS and Microsoft Academic data) Publish or Perish. As with impact factors, the strengths and weaknesses of this index have received critical scrutiny, and alternative measures have been devised to supplement it.^[39] One is the “G-Index,”^[40] which is the last rank at which the author’s *cumulative* citation count is at least the square of the rank. For example, moving down the ranks, the g -index = 10 when the total citations to an author’s top 10 papers equal or exceed 10^2 (i.e., 100), but not 11^2 (i.e., 121). The g -index takes into account the actual number of citations received at the top end, thus complementing the h -index, which is blind to this.

Organizational and national statistics. Increasingly, policy-makers consider bibliometric data as evidence in deciding how to allocate funds to scientific and scholarly organizations. Given past funding as input, organizational outputs can be assessed qualitatively by experts. They can also be assessed quantitatively through indicators such as counts of research publications and patents, and of their citations over time. In the hurly-burly of politics, where money and prestige are at stake, opinions on bibliometric indicators run from enthusiastic acceptance to litigious rejection.

The unit of analysis here is not individual authors but the organizations themselves. The Centre for Science and Technology Studies at Leiden University in the Netherlands is a world leader in research of this kind. The Centre’s former director, Anthony van Raan, notes that disciplines and specialties can be compared at the national level and across universities, faculties, and institutes. In his view, the studies most relevant for policy-makers are those that examine “the real ‘workfloor’ of research practice: departments, research groups and programs within universities and large institutes” (p. 21).^[41]

To learn a research unit’s international scientific influence, several ratios from WoS data are brought to bear. For example, to determine the impact of a German institute in medical research, van Raan’s team obtained 1) its mean citation rate per publication over a multiyear period (with self-citations removed) and for the same period 2) the mean citation rate of all papers published in all journals in the subject fields relevant to the institute. Dividing 1) by 2) gives the original “Crown Indicator,” a

measure of the institute’s internationally standardized citation impact in the Western world. If the ratio is around 1 (0.8 to 1.2), the program is average. A ratio of 0.5–0.8 indicates the program is below standard (less than 0.5 would be far below). Conversely, a ratio above 1.2 suggests distinction; above 1.5, high distinction. The German institute scored above 1.5, and the analysts could apply the same ratio to other programs in the institute to learn which contributed most to the excellence of its output. The Centre is engaged in ongoing improvement of the crown indicator, and a new one has been proposed.^[42]

Bibliometrics may yield insights for academics and policy-makers even when data are at the highest levels of aggregation. For example, Sylvan Katz^[43] compares nations within the world science system and finds that the number of papers they publish (“production”) and the citations those papers receive (“recognition”) have a very strong power-law relationship that is constant over time and independent of system size and nationality. This means that both production and recognition in science are inherently nonlinear or skewed, with small minorities of researchers producing disproportionately high numbers of papers and receiving disproportionately high numbers of citations. Science evolves this way naturally; its systems at all levels—regional, sectoral, national, and international—are “self-organizing” and “self-similar.” A major policy implication of this finding is that governmental attempts to change a nation’s science system through reallocations of funding are not likely to be simple or quick.

Other introductions to policy-related citation research in this vein are Leydesdorff^[44] and Lundberg.^[45]

INTERDOCUMENTARY RELATIONS

Citation analysts are not limited to counting attributes of documents taken singly. They can analyze counts of attributes taken jointly—for example, attributes of both citing and cited documents. It is in pairwise relations that analysis of citations may attain its greatest interest (see also Bar-Ilan, p XXXX). A nonexhaustive view of possibilities may be gained by looking at the two records in Table 3. (The Dialog Classic tags in them—CS, GL, and JN—are a bit clearer for present purposes than their analogs in WoS.) Table 3 shows the simplest pairwise link—direct citation, in which one document cites another. From that link, more complex structures can be created, such as the following.

The titles (TI) of citing and cited documents can be searched for coinciding vocabulary that suggests thematic connections. (No title words coincide in the records in Table 3, but the relations sketched here presume large pools of such records.) Data from the author (AU) field can reveal citer–citee patterns, including those of self-citation. The organizations that other organizations cite can be learned through corporate source (CS) data, which name

Table 3 Pairwise relations can be computed from raw data such as these

Cited document	Citing document
TI- The Artworld	TI- Farewell to Danto and Goodman
AU- Danto AC	AU- Margolis J
CS- Columbia Univ, New York NY	CS- Temple Univ, Philadelphia PA
GL- USA	GL- USA
JN- Journal of Philosophy, V62, N19, P571-84	JN- British Journal of Aesthetics, V38, N4, P353-74
PY- 1964	PY- 1998
DT- Article	DT- Article
SC- Philosophy	SC- Philosophy
LA- English	LA- English

authors' employers. The global locations (GL) of those employers permit similar analyses to be performed country to country. Journal names (JN) that a particular journal cites or is cited by—again including self-citations—are a standard bibliometric measure of influence. Publication year (PY) data, which are separable into cited and citing years, have multiple uses—for example, in WoS and Scopus statistics on authors and journals and in studies of document obsolescence. The PY variable can be combined with other variables in Table 3 to demonstrate chronological trends.

The last three fields suggest analyses parallel to those already described. In what proportion does each document type (DT) cite itself and other document types? What is the corresponding breakdown for languages (LA)? And finally, from what subject categories (SC) does a given research area receive citations, and to what SCs does it send them? SC data resemble those in import–export tables that quantify international flows of trade. They show the disciplines from which a field is importing ideas and the disciplines to which it is exporting them.

Intercitation. In studying intellectual connections, one can look at how members of a closed set cite each other. For example, among a set of aestheticians, how frequently does Margolis cite Danto or Danto cite Margolis over time? This is a rough measure of influence in the broadest sense. At this writing, Margolis has cited Danto in 11 articles, and Danto has cited Margolis in one. The citer–cited relation is asymmetric: A's citations to B need not be the same as B's to A.

Analysis of pairwise counts for a closed set of citers and citees—say, 20 philosophers in aesthetics—is a form of network analysis,^[46] and the methods available for studying social networks are perfectly adapted to it. With network software such as UCINET, identical techniques can be used to analyze the social ties, interpersonal communications, and citation ties of Danto, Margolis, and other aestheticians. If the nodes representing papers in citation networks are numerous, the researcher needs

software capable of analyzing and visualizing very large matrices. Pajek, which may be downloaded free, is one solution.

Intercitation is also of interest at the level of journals. Over some time period, for example, how many articles in the *Journal of Documentation* cite those in the *Journal of Information Science*, and vice versa? (This may bear on subscription decisions by serials managers in libraries.) Studies of intercitation among journals include Leydesdorff^[28,29] and Morris and McCain.^[47]

Bibliographic coupling. Originally proposed by M. M. Kessler,^[48] this measure is a count of the references that two publications make in common. (“Co-references” some call them.) Thus, if Paper A and Paper B cite two of the same other works, they are said to have a bibliographic coupling strength of 2. (Margolis's “Farewell” article and Danto's “Indiscernibility and perception: A reply to Joseph Margolis” have a strength of 2 because both refer to the same two books by Danto.) The fact that papers share one or two references may mean little substantively, but as their bibliographic coupling strength increases, so does the probability that they have similar content.

Bibliographic coupling is used in the Related Records module of WoS (see McVeigh, p. XXX). If one retrieves a publication of interest and wants to retrieve others like it, the “Related Records” button on its individual web page will call up other writings whose bibliographic coupling strength with the seed is at least 1. Unfortunately, such a low threshold retrieves many publications with no obvious ties to the seed. Moreover, the retrievals are based on only one seed at a time. To study *networks* of papers that are bibliographically coupled at a respectable strength, one must download records and use other software.

Cocitation. Whereas bibliographic coupling links *citing* documents, cocitation links *cited* documents. Bibliographic coupling is a static measure, because the references shared by two citing documents will not change. Cocitation, in contrast, is dynamic. It occurs whenever a later work cites any two earlier works in its footnotes or endnotes. Clearly, repetitions of the same pairing can occur in other later works indefinitely. Rousseau^[49] has a useful discussion of cocitation counts, bibliographic coupling counts, and their elaborations.

Cocitation is a symmetric relation; A's count with B is the same as B's with A. As with bibliographic coupling, a cocitation strength of 1 or 2 may mean little, but repeated cocitation of the same two works (especially if done by different citers) predicts high relatedness. In expository writings, the connection will usually be on grounds of subject matter, method (e.g., quantitative vs. qualitative), and form of knowledge. When dissimilar imaginative works such as *Moby Dick* and *Huckleberry Finn* are frequently cocited, the connections will be on deeper levels of inferred themes and meanings.

Even so, two works cocited in the same publication may have nothing to do with each other. This problem

has recently been addressed by weighting the tie between any two cocited works by the width of the narrowest text window in which the tie occurs—the narrower the window, the higher the weight. In other words, the more closely two works are cocited in body text, the likelier they are to be intelligibly connected. Text windows of course require access to digital documents in full, not just their reference lists. In Liu and Chen,^[50] which builds on Gipp and Beel^[51] and Callahan et al.,^[52] four degrees of cocitation proximity are weighted high to low: within the same sentence > within the same paragraph > within the same section > within the same article. The conclusion is that cocitations at *sentence* level preserve “the most important structural components in the traditional cocitation network” while reducing the size of the data set 20-fold (pp. 509–510). They are thus a more efficient unit of analysis than the far commoner but looser cocitation ties at article level.

Cocitation as a measure was independently introduced by Henry Small^[53] in America and Irina Marshakova^[54] in Russia. Both focused principally on pairs of scientific *papers* as their unit of analysis. Small soon collaborated with Belver C. Griffith et al.^[55] to develop algorithmic maps of science based on papers cocited above specific thresholds. Much subsequent work has continued to use papers to define scientific specialties. The early results are described in Garfield;^[17] more contemporary results, in the four reviews mentioned earlier.^[3–6]

With Griffith, Howard D. White^[56] introduced maps based on cocited *authors*. The data here are counts of the times any two authors are cited together in later publications, regardless of which of their works are involved. Put differently, they are counts of the times authors' oeuvres have been cocited. Karl Erik Rosengren^[57] anticipated this line of thought in Sweden by studying how frequently famous literary authors (e.g., Ibsen and Tolstoy) were “co-mentioned” in book reviews.

Cocited authors should not be confused with coauthors. Danto and Margolis, for example, have never coauthored anything, yet Arts and Humanities Search on Dialog Classic showed various items from their oeuvres cocited in 64 articles. Like papers, highly connected oeuvres tend to share subject matter or research methods or both. Once authors as oeuvres are connected, the analyst can also explore possible ties between the same authors as persons—for example, as mentor and student, coworkers, or intellectual opponents. Social facts like these often help to explain the groupings in author maps and heighten the interest of the maps to a field's insiders.

Katherine McCain began the cocitation analysis of *journals*.^[58,59] Her maps at this higher level of aggregation are based on how frequently any two journals are cited together, regardless of what in them is cited. Cocitation groups journals not on the basis of the superficial similarities perceived by indexers, but on conjoined use by researchers. Analysis can be limited to a specific

field or expanded to uncover supporting disciplines and related topic areas. It is therefore relevant to serials management and information retrieval.

Illustrating several of the possibilities, McCain has used journal cocitation mapping to study interrelationships in the literatures of genetics, economics, and aquatic sciences/fisheries. In the genetics and fisheries studies, visualization of the cocitation data demonstrated the existence of a basic-to-applied continuum of journals representing major themes in research and development. The genetics and economics studies combined cocitation data with intercitation data to identify, map, and cluster journals central to fields.^[13]

Cocitation analysis can be broadened to include *organizations* and even *countries*. Whatever the unit of analysis, algorithmically produced cocitation maps are usually quite intelligible. The same is true of maps based on bibliographic coupling. Zhao and Strotmann,^[60] for example, mapped a set of information scientists using their cocitation counts and their bibliographic coupling counts from 1996 to 2005 as separate indicators of relatedness. Both metrics proved informative and complemented each other. In another study involving many thousands of biomedical articles from 2004 to 2008, Boyack and Klavans^[61] found that an enhanced form of bibliographic coupling outperformed cocitation and direct citation in identifying clusters of documents at research fronts.

A cocitation map. Fig. 1 is a map of cocited information scientists. It was generated in 2004 by entering the name of a seed author, here Marcia J. Bates, into a web-based system called AuthorMap. This system was developed by a Drexel University team to visualize cocitation data instantly on the fly. At the time, AuthorMap was connected to Social Scisearch on Dialog Classic, and in the first step it retrieved the 24 other authors most highly cocited with the seed. In the second, it put these authors into a 25 × 25 matrix and retrieved the cocitation count of every unique pair. In the third, it used the Pathfinder Network (PFNET) algorithm to draw links reflecting only the *highest* cocitation counts among the 25 authors.

PFNETs are fully connected networks that simplify intellectual structure to its most salient aspects. The numbers above the links in Fig. 1 are cocitation counts. While Bates (lower center) is cocited with everyone in the map, her *highest* cocitation count is with Nicholas Belkin. Similarly, the highest counts for Carol Fenichel, Christine Borgman, Raya Fidel, and Karen Markey are with Bates. The same principle holds throughout the map—for example, the highest count for Amanda Spink (upper right) is not with Bates but with Tefko Saracevic. In this manner, the PFNET algorithm creates groupings that anyone familiar with information science can interpret.

Briefly, the central group around Belkin, which includes Bates and Saracevic, consists of authors associated with “the cognitive turn” in information science, which dates from the late 1970s. This group's goal has

Fig. 1 PFNET of top 25 names in Marcia J. Bates' citation image, with cocitation counts.

been to redirect research emphasis from systems to users, construed both psychologically and sociologically. Belkin, for instance, has explored the effects of ignorance (under the name "anomalous state of knowledge") on attempts to specify information needs to a retrieval system. Saracevic and the authors around him are keen on elucidating the notion of relevance in judging documents. Bates' group often study particular classes of persons (e.g., children, college students, humanities scholars) who seek answers from library catalogs or bibliographic databases in natural settings. The focus is on how users actually behave as they search online and what in system design helps or hinders their progress.

The cognitivists were reacting against the relatively impersonal tradition typified by the authors around Gerard Salton (upper left). Whether experimenting with retrieval from small testbeds of documents or appraising systems such as Medline, the latter group tends to stress algorithms, indexing vocabularies, and quantitative evaluations with formal measures like recall and precision. In their research, people function mainly as judges of system output and remain invisible otherwise.

Note, however, that the relationships of these cocitees are not so much adversarial as complementary. All seek to fill gaps in information retrieval theory and practice. Salton (symbolizing systems) and Belkin (symbolizing users) are here directly linked, and the entire field as mapped is ultimately generated from Bates' name. The cocitation metric and PFNET algorithm pack a great deal of historical information into a comprehensible whole.

Images, identities, and recitation. Fig. 1 is based on the top 25 names in Bates' "citation image." This term is defined in White^[27,62] as a rank-ordered list of the authors with whom a seed author is cocited. Citation images are

created by citers in general and give "the field's-eye view" of the seed author as it has developed across multiple publications.

The citers who create a seed's image can themselves be ranked by the number of publications in which they have cocited anything by the seed with anything by others. Given this fact, White^[27,62] calls them "citation image-makers."

Just as works and authors can be characterized by the number of citations they have received, they can be characterized by the number of *unique authors* who have cited them. The result is a new way of looking at impact. In the case of a work, do its citations come from many different authors or from relatively few authors who cite it again and again? A work with many different citers would seem to have had greater impact, in the sense that it has attracted more people's attention. Citer counts can thus reveal the intellectual *reach* of a seed author, which mere counts of citations obscure. In studies of American and British L&IS^[63] and then of nine fields in the natural and social sciences,^[64] Ajiferuke and colleagues used cited authors (rather than works) as seeds and counts of their unique citers as an impact measure. Although citation counts and citer counts were significantly correlated, the rankings of seeds they produce were not identical, and the differences were greater in the social sciences than in the natural sciences.

Another way to study a seed author is to obtain the author's "citation identity." As defined in White,^[27] this is not the field's-eye view, but that of the seed author. It is a list of the author's own citees, rank-ordered by frequency of citation over time. As the seed author's publications grow, some names will be cited more than once, and a fraction of these will be cited many times. These

Table 4 Names cited at least 10 times in Margolis's citation identity

Rank No.	Items	Term
1	48	MARGOLIS J
2	28	PUTNAM H

Rank: S1/1-85 Field: CA= File(s): 439. (Rank fields found in 77 records—510 unique terms).

heavily *recited* names are compact clues to an author's intellectual history. Almost always, the top name on the list will be the seed author's own: self-citation is ubiquitous in science and scholarship. Self-citation is no more egotistical than bylines are; it is the way in which authors bind their oeuvres into wholes, a task for which they are uniquely qualified.

We have seen that citations connect the philosophers A. C. Danto and Joseph Margolis. Danto's citation identity shows that he cites quite sparsely in his many journal publications. His single citation to Margolis came in response to the "Farewell" article in Table 3. Margolis, whose identity appears in Table 4, is much more prolific in his recitations. Names he cites 10 or more times reveal him to be a generalist of modern philosophy; aesthetics (represented in the identity by, e.g., Goodman, Danto, and Beardsley) is only one of his interests.

Until late 2013, citation images, image-makers, and identities were readily obtainable with the Rank command on the Dialog Classic system.^[62] Table 4 was made by forming the set of Margolis's 77 publications in Arts and Humanities Search (File 439) on Dialog and then entering a command that ranked his citees high to low. WoS has some useful modules for analyzing citations, but, unlike Dialog, not for obtaining images, identities, or cocitation counts of any sort. Nor do Scopus, GS, or Microsoft Academic. (The tools named in^[8-10] enable bibliometric map-pers to extract cocitation counts from downloaded data.)

Historiographs. Eugene Garfield and a programming team have patented a free, web-based tool called HistCite that makes "historiographs" possible.^[65] These show networks of citing and cited papers that define a specialty or

that descend from the influential work of a predecessor. Analysts choose the specialty (e.g., Digital Libraries) or the predecessor (e.g., M. M. Kessler) to investigate. The term "historiograph" indicates that the data, drawn from the WoS, can be graphed as a time-ordered cascade of papers whose linkages are pertinent to the history of a line of research. Certain papers stand out in historiographs because they have numerous links to or from other papers, suggesting a high degree of intellectual interest.

Although HistCite has its own graphics module, Fig. 2 is a diagram of HistCite data made with Pajek software. It shows a subset of the network of papers that descend from the original paper on bibliographic coupling.^[48] The downward-pointing arrows mean "cited by"—that is, the foundational work, labeled Kessler-MM-1963b, was cited by Garfield-E-1963, which in turn was cited by Garfield-E-1964 and so on. The chain Weinberg-BH-1974, Smith-LC-1981, and Liu-MX-1993 are literature reviews.

HistCite diagrams reveal not only direct citation links between papers but also indirect links—that is, connections through intermediary papers. In Fig. 2, the link between Brooks-TA-1985 and Chakrabarti-S-1999 (lower left) is not direct but runs through Lui-MX-1993 and Savoy-J-1997. Were this a chain of influence in the development of an idea, it might interest intellectual historians. Serious large-scale investigation of such chains will require computerized analysis of the full texts in which citations are embedded, but that is increasingly a possibility.

Long before HistCite, an important early historiograph appeared in a study that Garfield and two ISI colleagues made in 1964 on classic research in genetics. As reproduced in Garfield,^[66] the hand-drawn historiograph shows 40 interlinked papers keyed to major events in the development of DNA theory from 1820 to 1962. The baseline for the ISI study was a narrative history of this development, Isaac Asimov's 1963 book *The Genetic Code*. The ISI citation analysis independently corroborated Asimov's conclusions at many points. It also turned up intellectual connections he had missed but that enriched his history.

Through HistCite, existing data on many networks of papers are also freely available on the web. The linked HistCite Guide explains the pertinent variables and the algorithmic mode of visualization. New analyses may be conducted on data downloaded from WoS.

Recently, van Eck and Waltman^[67] have introduced another free tool for analyzing and visualizing citation-linked chains of WoS documents. Called CitNetExplorer, it can interrelate papers historically, cluster them by topic, and reveal papers new to the user for retrieval.

Documents by the millions. Klavans and Boyack^[68] is a succinct history of attempts to make citation-based subject classifications more accurate. At the same time, it captures the gradual transition to "big data" in the visualization of scientific and scholarly knowledge. Researchers today can map data sets involving millions of documents (e.g.,

Fig. 2 Histogram of papers descending from Kessler's paper on bibliographic coupling.

Waltman & van Eck^[69]). Some of their achievements are on colorful display in two large, handsome atlases by Katy Börner.^[70,71] The best-known visualization at present is perhaps Klavans and Boyack's beautiful map of the interconnectivity of all science.^[72] Originally drawn from 7.2 million papers in more than 16,000 journals covered by WoS and Scopus during 2001–2005, it has since been extensively updated.^[73] It depicts a network in which the nodes represent *groups of journals*, and the links represent intercitation among the groups. Strong intercitation connotes highly shared literatures and thus defines disciplines (e.g., physics) or specialties (e.g., brain research) for color-coding. Weaker intercitation connotes literatures shared *across* fields; fields with considerable sharing (e.g., physics and mathematics) are adjacent in the network, while fields with little or no sharing (e.g., brain research and earth sciences) are apart. The network also serves as a base map against which aspects of particular disciplines or specialties (e.g., funding) may be highlighted and compared.

CONTENT, CONTEXT, AND IMPACT

Can we finally say what citation counts mean? This question has long been debated—especially whether citation

counts can be taken as indicators of quality. That is what the persistent calls for “a theory of citing” are all about.

The root of the problem is that counts treat citations as identical units, when clearly they are not. First, as pointed out in Cronin,^[74] counts hide the fact that citations refer to writings at different levels of granularity, from entire oeuvres down through individual works, passages, and sentences to single words and numbers. Second, counts mask the disciplinary provenance, subject matter, and genre of citing works. Third, they also mask the varying functions of citations in context. There are differences between identifying one's theoretical tradition, adopting a method, suggesting background readings, acknowledging a mistake, nailing down a quote, and so on. Fourth, counts may be increased by negative citations that reflect adversely on what is cited. Fifth, counts often merge self-citations with citations to other authors. Sixth, counts fail to discriminate between citations that are essential to a new text and citations that could be dropped from it without loss. Seventh, counts may include citations to works the citers have not even read. Eighth, works that citers typically leave uncited—reference books, popularizations, technical manuals, and the like—cannot accumulate counts and so be recognized. Worse, omissions of this sort may occur with important substantive works—works that

should be cited. Ninth, counts are unrevealing as to citers' deeper intentions: Are they simply crediting intellectual predecessors? Symbolizing concepts? Marshaling everything relevant to their topic? Showing off their erudition? Summoning authorities to persuade readers of their own credibility? Inflating the citation counts of cronies from whom they expect the same?

This multipronged critique requires that citations be analyzed as to their contexts and content—their implicit as well as explicit meanings. It requires that citations be categorized in various ways and then recounted. In what is called “citation content analysis,” researchers extract *explicit* phrases from the text surrounding citations in multiple documents. They are looking for stable meanings that emerge as the phrases pile up.^[75] Ding et al.^[76] describes techniques that are emerging in this long-standing area of interest, since, in some fields at least, citations mark passages whose rhetorical significance is algorithmically detectable.^[77] One possible goal is simply to improve citation indexing, such as giving text-based clues as to *why* writings were cited and at what level of granularity. A more immediate goal is to discover linked knowledge claims in citing documents by extracting phrases from the sentences in which citations are made. Information scientists have begun to use such micro data to automatically summarize individual texts and to produce literature reviews across texts (Small–Elkiss et al.^[78–80]).

In another line of inquiry called “citation context analysis,” researchers must discover the *implicit* relations between citing and cited texts, such as what citations accomplish and the motives behind them.^[77,81] Studies of this sort traditionally require extensive reading and inference by human judges. Two examples: Garfield^[17] reproduces an early set of 15 inferred citer motives; among them are crediting related work, identifying methods and equipment, providing background information, and substantiating claims. Another influential work, by Moravcsik and Murugesan,^[82] calls for decisions such as whether the cited work is essential to the citer's new argument and whether the citer's attitude toward the cited work is positive or negative. Despite the growth of automated analyses, findings from older, labor-intensive studies like these have not lost their relevance (see, e.g., Baird,^[18] White,^[77] and Small–Nicolaisen^[83–87]). Some conclusions to be drawn from reviews of citation analysis are as follows:

- Relatively few citations are negative, and negation is also judged inconsistently across studies; it comes in many degrees of severity. (“Smith is wrong” is clearly a negative citation, but what about “Smith only partially covers my topic”?) Moreover, the negative citers may themselves be wrong. Even if they are not, to criticize something is by no means necessarily to destroy it. Controversies are frequently worthwhile; indeed they are a major driver of science and scholarship.
- While relatively many citations are indeed “perfunctory,”^[82] this does not mean they are useless. They do things like ritualistically invoking a pioneer, providing background reading, or mentioning distantly related work. Their opposites, which Moravcsik and Murugesan^[82] call “organic,” identify writings to which the new writing is directly indebted. These, too, are numerous. A possible predictor of organically related writings is multiple references to them in the same text.^[26,88] Another is an author's relatively heavy recitation of them over time.^[27]
- Works may be repeatedly cited because they symbolize concepts.^[75] For example, chemists can allude either to “hydrogen scattering factors” or to “Stewart et al.” and mean the same thing. Occasionally, a paper comes to stand for more than one concept,^[89,90] and full-length books may stand for many.^[91] When citations are inconsistent in what they connote—an unpublished study has shown this to be the case for citations to Wittgenstein's *Philosophical Investigations*—citors are referring to different passages or interpreting the same passages differently.
- Self-citations are no less legitimate in function than other kinds.^[27,92] If evaluators see self-citations as a problem, existing software can remove them from counts. For some measures (e.g., eigenfactor scores), removal is automatic.
- Authors may sometimes cite items without checking or even reading them. Clerical errors can be traced to the blind copying of flawed secondary sources.^[87] More seriously, cited works may be misrepresented as to content.^[93] But imperfections like these should not detract from the many millions of citations that function properly.
- The supposed norm in science and scholarship that “all relevant materials should be cited” means that authors should pay known intellectual debts and not suppress contrary evidence. In practice, authors do not take “all relevant materials” literally. If they did, lists of references would be too long for journals to accommodate. For example, no foundational work could ever be, in Merton's sense, incorporated and obliterated. To discredit citation counts, MacRoberts and MacRoberts^[94] claim that relevant materials are grossly undercounted, arguing that authors cite only about 30% of them. But this percentage depends wholly on the MacRobertses' own relevance judgments, for which they offer no supporting data. By second-guessing what authors *should* have cited, one can arrive at any percentage whatever.
- Social constructivists, for example, the MacRobertses,^[95] assert that the true motive of citers is to borrow prestige for their own texts from big-name authorities and to ingratiate themselves with editors, referees, and colleagues who can return favors. This is a bald form of the “persuasion hypothesis,”^[96,97] which holds that

authors cite to persuade others to accept their works. Undoubtedly, authors want to be persuasive—how could they not?—and cite others to achieve that goal. But are they trying to manipulate readers underhandedly, or are they simply giving proper credit? The latter view—called “the reward hypothesis”—is associated with Merton and his school of sociologists of science. Where statistical evidence has been gathered, it supports the Mertonians rather than the constructivists.^[87,98] In fact, the constructivists rarely present hard evidence; their case is closer to satirical folklore. The most trustworthy critics of citation analysis are those who have actually done it.

The issue, once again, is how seriously to take citation counts as indicators of quality.^[99] Cautionary examples include Gregor Mendel, whose now-famous work in genetics was relatively little cited until years after his death, and Arthur Jensen, who is highly cited but whose writings on race and IQ many academics deplore because of their implications for American education. With regard to Mendel, there are indeed cases of delayed recognition in science—van Raan has called them “Sleeping Beauties”^[100]—but they are rare. According to Glänzel and Garfield (p. 8),^[101] “Nearly all significant research is well cited within the first three to five years of publication.” Jensen is a somewhat ironic case in point: his foes quickly and repeatedly attacked his research to keep it from influencing policy-makers. But no one has been swayed simply by his citation rate. As Garfield (p. 652)^[102] puts it, with Jensen in mind, “Not all high impact science is great science.”

The word *impact*, in both the cognitive and social sense, is the best name for what citation counts measure. Work deemed bad for one reason or another may still have high impact. Conversely, good or even excellent work may have little or no impact, at least for a while. However, cases like Mendel’s and Jensen’s are exceptional. The trick for interpreters of citation counts is not to lose sight of the norm: high citation impact is frequently correlated with high marks on other scales, such as a favorable peer review^[103,104] and receipt of prizes and awards.^[99] As citationists themselves point out, counts should be compared only within disciplines and checked against other measures, but they are no less informative for that.

They are in some ways like election results. Delving below vote totals, one finds that voters differ in their affiliations and demographics, that different issues motivate them, that not all are equally well-informed, that ballots contain mistakes, that ballots may be fraudulent, and so on. Nevertheless, vote totals by themselves determine the central fact in all political battles—who wins and who loses. Citation counts, too, can be broken down in many interesting ways, but none is more interesting than what they reveal as aggregates—the current standing of works, authors, journals, and organizations in the battle for attention.

Citation Indexes and the *Web of Science*

Marie E. McVeigh

JCR and Bibliographic Policy, Thomson Reuters - Scientific, Philadelphia, Pennsylvania, U.S.A.

Abstract

The *Web of Science*, an online database of bibliographic information produced by Thomson Reuters—draws its real value from the scholarly citation index at its core. By indexing the cited references from each paper as a separate part of the bibliographic data, a citation index creates a pathway by which a paper can be linked backward in time to the body of work that preceded it, as well as linked forward in time to its scholarly descendants. This entry provides a brief history of the development of the citation index, its core functionalities, and the way these unique data are provided to users through the *Web of Science*.

INTRODUCTION

In 1997, the Institute for Scientific Information (ISI[®], now part of Thomson Reuters) released the *Web of Science*, an online database of bibliographic information. It currently contains records from more than 13,000 journal titles spanning nearly 110 years of published information in the physical, chemical, natural, and applied sciences, all aspects of the social sciences, as well as the leading scholarly publications in arts and humanities. The library and scholarly communities immediately recognized that the hyperlink and search capabilities of the Internet could simplify the retrieval and navigation of scholarly information. The origin of the *Web of Science* and its real power, however, lay in an older and more radical innovation in information—the scholarly citation index. A citation index is a specific type of bibliographic and bibliometric database that has a specific structure and functionality. In this entry, I will outline the fundamental concepts of the citation index as well as describe how the *Web of Science* uses the key insights of citation indexing to offer both simple and powerful tools for the retrieval, navigation, management, and analysis of scholarly literature.

The primary uses of the *Web of Science* center on its structure as a citation index, containing an extensive, selective index of source materials, and an index of cited references. A simple topic or author search will present a user with a set of articles. The record for each article contains a list of the works referenced by the author, giving a look backward in time to important, relevant materials. It also contains a link to works published subsequently that reference the earlier article, giving a look forward in time to how the earlier article was interpreted by the scholarly community. Because citation searching retrieves articles based on relationships created by scholarly authors, it does not require subject vocabulary. It is possible to research an area that has emerging and complex terminology, without having to search on all that

vocabulary. Citation searching can also bypass ambiguous terms that are shared among several fields. Finally, the cited reference index, which allows a user to search all references in the database, enables a thorough analysis of citations, even if the cited materials are not part of the source database.

THE REVOLUTIONARY IDEA OF CITATION INDEXING

Among the most fundamental activities in research are collecting and comprehending the current knowledge. Thus the practice of citing prior literature is closely bound to the practice of scholarship itself. For the author, the list of cited references assembles a body of prior works within which the context of the current report can be considered. It is a way to acknowledge the shoulders of the giants on which you stand, either to climb higher, or to identify the point from which you depart. For the reader, pursuing the cited materials is a way to begin a guided exploration of the literature, to deepen understanding of the current work, and to inform the process of intellectual critique that allows the creation of the next scholarly work.

Eugene Garfield realized that the references created in the process of scholarship could construct a unique bridge between the creator of information, the author, and the consumer of information, the reader.^[1] Cited references were highly informed connections between scholarly works created by the scholars themselves, that could provide an authoritative statement of relevance. These connections were already available in each article, but could only point backward in time. The key insight underlying the citation index is that, when collected across many papers, cited references can connect an earlier work to many subsequent works, reframing the paper in terms, not of its origin, but of its consequences. If the cited references in a paper are descriptors added by the author, the citations to a

paper are descriptors added by later scholars that can indicate the developed meaning of the work.^[1,2]

At the time of writing a paper, there is no way for the author to anticipate fully the later development of the ideas or methods contained in his/her current description. By codifying the retrospective sweep of each work, and by linking many later works to the original work they all cite, a citation index creates a pathway by which a paper can be linked forward in time to its descendants. Through this, the community of publishing authors became what Garfield called “an army of indexers” providing information about their own and others’ works, and far exceeding the productivity, capacity, and expertise of any group of subject indexers. In a more modern parlance, citing authors are tagging each prior work by relating it to their own paper. Garfield’s goal was to create a new method of document collection and indexing that would harness this highly informed tagging to improve information retrieval. His solution was to create a citation index.

WHAT IS A CITATION INDEX?

In its simplest sense, a citation index is a structured list of all the cited references from a defined collection of original source materials^[3,4] and organized so that each cited reference can be associated with the article(s) that cite it. A citation index for a single article would thus be a list of cited references and the information about the article in which they appeared. A citation index for a journal would then be a list of all the substantive texts (exclusive of marginalia, advertisement, and similar content), along with the cited references that appeared in these texts.

Immediately, the complexity becomes apparent, as several articles in a journal could cite the important prior work. This shared citation, indicative of a topical relationship among the works, would be visible in the citation index in a way that is difficult to capture by reviewing the reference lists of each article individually.

A true citation index has two aspects—a defined source index and a standardized/unified cited reference index (Fig. 1).

The defined source index is a fully described set of materials from which cited references will be compiled. It can be a list of articles that is collected by subject and timespan, or a list of journals or other materials from which articles are drawn. In all cases, the content must be clearly defined bibliographically and temporally. Without clear definition of the source materials, the meaning of the citations themselves becomes unclear and they are of limited use. Selecting a random set of articles across subjects and across time results in a collection having no clear meaning and very limited utility.

The standardized cited reference index is the set of cited references that appear in the source material. The cited references are not harvested as they are presented in the journal, as journals will vary in the information and format they require for each cited reference. Rather, in the construction of the index, data elements from the references are standardized to allow like citations to be collected, or unified.^[5] Citation unification allows all articles that cite the same reference to be collected, thus visualizing the relationship among them that is implied by the reference. The functionality of a true citation index depends on these two interconnected databases and will be discussed in detail below.

Fig. 1 Creation and structure of a citation index. A citation index is derived from a two-part indexing of source materials. Bibliographic entries are created for each source item; cited references are captured into a separate index where identical references are unified. The resulting two-part structure is the basic architecture of a citation index.

In 1963, the first robust, multidisciplinary implementation of a citation index was published commercially as the *Science Citation Index* (SCI). The first printing used a source index created from 613 scientific, technical, and medical journals and all substantive materials published in those journals in the year 1961. The cited reference index contained more than 1.4 million cited references. The intricate methodology needed to navigate the several print indexes^[3] did not prevent information scientists' recognizing the unique utility and great potential of the SCI, not only for retrieving an exhaustive (if exhausting) list of articles relevant to a subject, but also for navigating, mapping, and evaluating the research literature.^[2,4,6-9]

THE FUNCTIONS OF CITED REFERENCES IN CITATION INDEXES

The conceptual and practical applications of the scholarly citation index as envisioned by Garfield in the 1950s waited more than 40 years for a technological advance that would radically transform their use. When the maturing Internet met the "hyperlinked, relational database" that underlay the ISI citation indexes, the potential of Garfield's novel concept was finally realized. In 1997, ISI[®] (now a part of Thomson Reuters) released the first version of the *Web of Science*, containing the *Science Citation Index-Expanded*, the *Social Science Citation Index*, and the *Arts & Humanities Citation Index* in a single interface. When the citation indexes were mounted as a fully searchable, hyperlinked, relational database, the real power of the citation indexes was suddenly very simple to use.

Before describing the *Web of Science* product, it is necessary to describe the key functions of a citation index. A true citation index attaches three functions to cited references as an aspect of the scholarly literature: cited reference capture, cited reference linking, and cited reference searching, each being dependent on the effective implementation of the one prior to it.

Cited Reference Capture

Cited reference capture is the inclusion of the cited references as an aspect of the bibliographic data for each source article in the source index. An increasing number of bibliographic resources, such as databases, aggregators, and institutional or subject-specific archives, provide cited references as part of the data associated with each article. In addition, many publishers, in moving to electronic access to journals, freely provide not only table of contents of issues, but also the abstracts and cited references of articles, making much of this information readily available. The cited references provide additional information about the content of the indexed item in that they sketch the context in which the author is placing his/her work.

Besides this subtlety of indexing or cataloging, the presence of cited references allows a citation index to echo a critical aspect of how researchers interact with the literature when they review the full text: author, title, abstract, and a perusal of the cited references allow a more informed decision about the importance of obtaining the full text for close reading.

Cited Reference Linking

The most basic and most important function of a cited reference is allowing the reader to locate the particular works cited and to expand his/her knowledge of the subject area, as well as, in some sense, to retrace the intellectual or methodological path taken by the author. Cited reference linking was a natural extension of capturing and providing access to cited reference lists. A cited reference is, by its nature, a link to the prior literature, even in a print journal or in the print SCI. In electronic resources, this link can be made literal, functional, and immediately navigable, thereby expanding the role of cited reference capture in online information resources, both bibliographic and full text. The creation of a navigable link to the citing works allows a scholar to view not just the antecedents of a work, but its descendants. Citation linking allows each article to collect a continuously evolving set of user-generated commentary in the form of citation acknowledgment.

Cited reference linking is limited by three things: availability of content, correctness of cited references, and effectiveness of linking methodology.

Cited reference linking is first limited by the content of the resource in which the link exists. If the material being cited is not resident in, or is not available to, the resource, no functional link can be created. Publishers will often provide links to/from only those materials that are also resident on their sites. Bibliographic databases can link from an article record to another article record in their holdings, or suggest a link to an external source. However, the number of links to an article (the citation count) that can be assembled and navigated will be determined by the publication sources from which these citations were captured. If the cited reference was not captured, or the source item is not available, no link can be made. For example, if a specific book is not indexed as a source item, and its cited references are not captured, the book will not appear as a citing item for any record in the database, nor will there be a bibliographic record for the book that can collect all the citations to the book. Because the importance and volume of books in scholarly communication will vary somewhat by subject area, the absence of these links will affect scholarship and bibliometrics in some fields more than others. Scholarly books are less prominent in the physical, biomedical, and applied sciences than in the social sciences or the humanities, but their role in the latter fields can be critical to fully understanding the current research.

Secondly, cited reference linking is limited by the correctness of the bibliographic data in the cited reference itself. Many studies have examined the occurrence of citation errors in the primary literature as well as in citation indexes and speculated about their source.^[10–13] The advent of online journals both enabled and, in some ways, complicated cited reference linking. While the online form of a journal can support a live link to cited works, the relatively new and still-evolving bibliographic metadata associated with electronic materials create some confusion among authors as to the correct citation. The familiar data elements of author, source title, volume, page, and year (and possibly other elements) have given way to article numbers, electronic pagination, summary-versus-complete versions of a text, preprint versus published versions, HTML, PDF or print versions, and so on. Some electronic journals eschew volume or issue numbers, pagination or article numbers, leaving authors with a host of numbers they can attach to a reference in an effort to link their reader to a prior work. This leads to an increasing diversity of ways a given work is cited and hinders the creation of links. The Digital Object Identifier (DOI) foundation (<http://www.doi.org>) offered a solution that seemed simple and powerful, given that it originated in an online publishing environment for the use of online publications. The DOI is a unique and permanent identification of a document. It is associated with the document itself, not its electronic location, so it can be used to create a links to any and all places where the document might reside, such as a journal Web site, an online repository, an author Web site, etc.^[14] The advantage of the DOI is that it is machine-readable and designed for an electronic, Web-based navigation. This is also something of a disadvantage in that the DOI is not human-readable. A single character error in a DOI is both fatal and undetectable in the way a similar error in a journal title is not. It is not often that a citation to the *British Medical Journal* would go unnoticed and uncorrected, nor would it usually prevent a reader from seeking out the article in the *British Medical Journal*.

The third and most problematic limitation on cited reference linking has to do with the linking methodology. How robust is the system in overcoming citation errors and in its ability to locate the correct material even when the cited reference provided is incorrect? A reference to an incorrect author, or some error in source, or page, or DOI results in a citation that is not linked to the source item, and so is not visible in the Cited By links on that source item. When cited reference linking is the only way to retrieve citing articles, an incorrect reference is a lost reference.

Cited Reference Searching

Direct search within the cited references is the most powerful (and possibly the least utilized) function of cited references, as it requires a true citation index to be most

effective. Often it is assumed that cited reference indexing and cited reference linking are all that is required for a citation index, but there are important differences. A cited reference search operates on the structured, standardized data in the cited reference index, independently of the source index. The separate index of cited references is the critical distinction between a citation index and a bibliographic resource with linked cited references, but lacking a searchable cited reference index. Cited reference searching allows the feature of cited reference capture to break through the limitations of cited reference linking. To find materials that have cited an item in a bibliographic resource that lacks a cited reference index, you can locate the source item and navigate to the linked cited references, but you will have no way to find the items when citation or linking was imperfect. An incorrect citation to this article can only be found if you happen across the misciting article and peruse its reference list and recognize the unlinked, but familiar cited work. This is, ironically, no different from the problem of finding such citing works prior to the creation of the SCI, when even the most rigorous literature review could not identify all citing works.

Further, cited reference searching is a way to overcome the inevitable incompleteness of any individual source index. A citation index, through cited reference search, can collect all materials in the source index that cite a work, even if the work itself is outside the source coverage. For a bibliographic database without cited reference searching, comprehensive coverage is indispensable for citation analysis, as effective analysis is limited to those works that are in the source index. However, no matter how monumental the coverage, it will be insufficient if the item of importance to the searcher is not a source item. No matter how large the source index, cited references can only be collected to other items in the source index. With cited reference searching, the boundary around the coverage is less fixed. The searchable cited references provide pointers to external sources, which are then available to collect and to quantify.

Cited reference searching becomes more critical for scholarship in fields where the complete source materials cannot possibly be covered. In the natural sciences, citations to GenBank or the arXiv preprint server form an important part of the literature. In the social sciences, cited materials can include not just journal articles, books, and conference proceedings, but additionally demographic and census data, government reports, newspapers, and other ephemera, and a complex array of grey literature source materials. Even more problematic is scholarship in the arts and humanities, where materials cited can include original works of art, specific performances, primary and historical works, and a host of multimedia online resources. These works are critical for scholars, and so are critical for scholarly communication, but they usually defy indexing as source materials.

The enabling reach of cited reference searching reveals a logic to the selective development of a source index. Although Garfield meditated on the possibility of achieving H.G. Wells' vision of a "World Brain" of all knowledge,^[4] and despite the incomprehensible enormity of the Internet, no perfect, comprehensive, all-inclusive resource is on the immediate horizon. However, repeated works have confirmed Bradford's law that 80% of scholarly references are to 20% of source journals. This logic underlies the selection of source materials for the earliest productions of the *Science Citation Index*, as well as the current expansion of the Thomson Reuters indexes to include journals that publish more nationally and regionally relevant scholarship.^[15,16] Knowing that the source literature providing the citations has been studied and selected for both quality and representational breadth provides the user confidence in the value of the citations.

THE WEB OF SCIENCE AS A CITATION INDEX

Content

The *Web of Science* has, as its backbone, a suite of citation indexes spanning more than 100 years of published literature in a wide array of subject areas. The *Science Citation Index-Expanded* contains the *Century of Science* back file, and so indexes both source materials and cited references back to the year 1900. The *Social Science Citation Index* currently begins in 1956, but a *Century of Social Science* file back to 1900 is in preparation. The *Arts & Humanities Citation Index* includes materials back to 1975. The source index for these databases includes nearly 41 million items from more than 13,000 titles. The citation index includes 600 million indexed cited references, which resolve to approximately 155 million unified cited references. In the years since its first release, the *Web of Science* has added other data sources to expand the citation index. These include *Index Chemicus* (from 1993 to the present), *Current Chemical Reactions* (with an expanded file back to 1850), and, in fall 2008, the *Conference Proceedings Citation Index* with 10 years of published papers from scientific and scholarly meetings. The content of the *Web of Science* is updated weekly with between 20,000 and 60,000 new source records and up to 1 million cited references.

Source Records and Searching

The *Web of Science* was redesigned in 2007 to allow a deeper integration with the other databases in the *ISI Web of Knowledge* platform. The enhancement retained all the key functionality of the *Web of Science* interface, with improved navigation to the most-used features, additional functionality, and a more streamlined search process. The source index can be searched by topic (a combined search

field that includes article title, author keywords, *KeyWords Plus*[®], and complete author abstract), article title, author (individual author or collective, corporate, or group author), publication name, year published, address word, language, or indexed document type. The interface allows a simple text string entry, but more experienced searchers can use Boolean logic either within a search field or to combine multiple fields to create intricate and precise searches. The Advanced Search option supports command-line searching that is familiar to many information professionals. Specialized searches for specific chemical structures are enabled using a plug-in. Both General Search and Advanced Search allow the user to limit searches to specific databases and/or time intervals (such as latest week, or 2 weeks, year to date, or just the past 5 years).

Several features in the search page provide assistance and information for users who may be unfamiliar with searching structured data. Search Aids are activated by a link located to the right of the search box when an appropriate field is selected. The Search Aid will provide access to the index terms in that field, collected across the entire database, and will allow users to add precise, specific terms to their search with a click. The Author Finder tool guides the user through a series of search steps to facilitate locating the works of an individual author. Author searching was further enhanced by the addition of the Distinct Author Sets feature, which uses advanced bibliographic analyses across the entire *Web of Science* citation indexes to cluster source items that are likely written by the same author.

Cited Reference Searching

Cited reference searching is a two-step process. Because the very strength of cited reference searching lies in the ability to surface unlinked, imperfect citations or citations to materials not included in the source index, some flexibility in the search terms is important. First, the user enters one or a combination of the following elements: cited author, cited work, and cited year. Understanding that cited references can be presented in various ways (for example, author names with or without a first initial, variations in the abbreviation of the title of the cited work, etc.) suggests the use of truncation and wildcards to retrieve the errant cited references. The user is then presented with a list of records from the cited reference index that match the criteria. Selecting items from that list according to one's understanding of the variations in citation allows a more complete retrieval of citing articles. Finishing the search will then display a list of the citing articles.

For example, R.J. Charlson wrote an influential paper on global warming, published in the journal *Science*.^[17] Searching for Cited Author = Charlson and Cited Work = Science retrieves a large number of variants for this

search, some of which clearly show errors in cited author, cited volume, or cited page (Fig. 2). To date, 1242 citing articles are linked to this record, but an additional 42 citing articles can only be retrieved using cited reference searching. This is a simple cited reference search, where the goal is to retrieve all items citing a known article. Cited reference searches using author only can be used (with care) to collect all articles citing any of the author's papers. Using Advanced Search (or the Search History page), one can combine that cited reference search with an author search using the Boolean operator NOT. This will give a list of articles citing Charlson's work but for which Charlson was NOT an author, i.e., a count of citing articles that excludes the author's citations to his own work.

Cited reference searching in the print SCI was meticulous work, cycling from the source indexes to the cited reference indexes and back, pulling multiple volumes off

the shelf of imposing orange volumes. Although moving this activity into an online environment made it easy, cited reference searching still requires some effort on the part of the user. Clicking a link in the *Web of Science* or in other electronic resources is so easy that it distracts most users from any other method of locating citing articles. Even the most powerful linking methodologies and the most extensive coverage of source materials will have missing links and lost references, blind spots, and gaps. Thorough scholarship still requires a thorough search.

Search Results and Results Navigation

The results list from any search is not a flat list of records, the end point of a search, but a functional list of items that can be a starting point for a greater understanding of the network of literature available. Lists of results may be sorted by latest date (most current records presented first),

Cited Author	Cited work	Cited Year	Cited Volume	Cited Page	# of citing papers	Link to source record
CHARLSON	SCIENCE		255	423	1	
CHARLSON	SCIENCE	1992	255	423	2	
CHARLSON R	SCIENCE	1992	255	6423	1	
CHARLSON RJ	SCIENCE	1992	255		1	
CHARLSON RJ	SCIENCE	1992	255	254	3	
CHARLSON RJ	SCIENCE	1992	255	422	23	
CHARLSON RJ	SCIENCE	1992	255	423	1242	View Record
CHARLSON RJ	SCIENCE	1992	255	424	1	
CHARLSON RJ	SCIENCE	1992	255	425	1	
CHARLSON RJ	SCIENCE	1992	255	2423	1	
CHARLSON RJ	SCIENCE	1992	225	423	2	
CHARLSON RJ	SCIENCE	1992	43	152	3	
CHARLSON RJ	SCIENCE	1992	25	423	1	
CHARLSON RJ	SCIENCE	1992	25	426	3	

Fig. 2 Cited Reference variants. Citation variants for the search Cited Author = Charlson and Cited Work = SCIENCE. A total of 43 cited references for this author and work were retrieved. The 14 references above represent those that are likely to be citations to the same article. The cited reference in bold represents the item where cited reference linking was successful. In these results, 1242 citing articles are linked to this source, representing 96% of the citing articles.

times cited, relevance, first author, source title, or publication year. The sort options facilitate the navigation of large and small results lists, rather like shaking a box of cereal to get the prize to float to the top.

The Refine feature allows the user to manipulate the set of results to eliminate or to focus on records that contain some item of particular interest. Refine will display the count of records within the set of results according to subject area (the index categories, or *Journal Citation Reports* categories), document type, author (from all authors, not just the first author), source title, publication year, institution, language, or country/territory. The various Refine options can be used singly or in combination. For example, using Refine by document type = Review and by publication year = 2007 or 2008 will winnow your results set to display only review articles from the past 2 years.

The Analyze feature uses the same data elements as Refine, but allows the user to characterize the set of retrieved records as a whole entity. While also supporting the same kind of filtering as Refine, this view of the data allows bibliographic analysis of a search set, by displaying not just numbers of records according to the selected field, but the percentage of records in the results set that contain this element (Fig. 3). For example, a search on Topic = “global warming” retrieves 8037 records (as of this writing); analyzing this group by publication year shows the emergence of the specific term in 1975. No other papers using the term appeared until 1981, but fewer than 10 papers per year were published through the remainder of the 1980s. The number increased to 40 papers in 1989, then jumped to 151 in 1990. The term, and presumably, the more general field of the study of climate change had a steady increase in publication activity through the 1990s, and early part of the new millennium. In the year 2007, more than 940 papers using the term were published, a number likely to be equaled or exceeded in the year 2008.

Users can also highlight the institutions, journals, and authors that have made the greatest contribution to the literature. Result sets of up to 100,000 records can be navigated using Refine and Analyze.

The Citation Report creates a rapid overview of several bibliographic analyses for any results set (up to 10,000 records). It includes graphical display of the number of items in each publication year, as well as the number of citations in each year. Basic bibliometric data are created for the set, such as the sum of all times cited, a link to all the citing items (with or without citing articles that are, themselves, part of the results set), the average number of citations per item, as well as the emerging metric, the h-index.^[18] It displays the list of results, as well as the citations per year for each (Fig. 4). The analyses in the Citation Report can be printed or e-mailed or the data can be exported as a delimited file.

The Bibliographic Full Record

Although the manipulation and review of large sets of results is an important aspect of information retrieval, the *Web of Science* is first and foremost a database of bibliographic records, connected and navigable by citations. Each record in the *Web of Science* contains all basic bibliographic and Thomson Reuters' indexing metadata, but the record has evolved from its early form as a flat bibliographic entry in the *Science Citation Index* to an information node that is linked to a wide array of internal and external resources (Fig. 5). A simple and powerful use of the Internet enables a user to link directly from the *Web of Science* bibliographic record to the full-text record in journals for which the library holds an electronic subscription. However powerful the bibliographic data, scholars require the full text to fully comprehend and use an article.

Full records also include a link to the captured cited references as well as to the citing articles—through the Times Cited (and Cited By) links. This allows the immediate collection of the citing articles as a results list. There is a deceptiveness to this simple retrieval. The citing articles are obviously related to the work at hand, but they will also be subtly related to one another. For example, an article describing a specific method or technique in biochemistry can be cited by other works in various experimental systems. The citing articles may share no keywords or title words, but their common use of the original technique means that each is likely to add some incremental insight to the method, including caveats or modifications that may be of great use to other, later scientists seeking to replicate or apply the method.

Cited Reference and Cited By links can be enabled even in resources that are not citation indexes. However, *Related Records*[®]—another feature available on each bibliographic full record—is a higher order function built on the cited reference index itself. *Related Records*[®] uses a method called bibliographic coupling,^[19,20] in which the cited references in the starting document are used to retrieve all other materials that share at least one of those cited references. A citation index is derived from the insight that the list of cited references in each article functions as a set of bibliographic descriptors provided by the author; therefore, if two authors cite several identical references, it suggests that the source items are related. These relationships might not be revealed from standard topic searching, nor are the articles necessarily directly connected by citation linking. Because the cited references are available at the time of indexing, *Related Records*[®] can be linked long before any later citing papers appear. This allows a record to expand into a broader literature immediately upon indexing while the development of a citing article context is still evolving. Enabling the retrieval of relevant articles through these more subtle relationships was one of the first goals in creating the citation index.^[1]

Fig. 3 Section of the Analyze Results screen. The search Topic = “global warming” retrieved 8037 records; the figure shows the results analyzed by publication year. Selecting a publication year and using View Records filters the results.

In 2008, a long-awaited feature was added—in a beta version—to the full records in *Web of Science*. The Citation Map creates a visual representation of the cited references and/or the citing articles that are connected to the starting record. The feature was recently reviewed by Simboli^[21] and will not be discussed in detail here. Visual display of citation relationships is complicated when the number of citation links is very large, and of limited use when the number

of citations links is very small. The *Web of Science* dataset is rich, deep and densely linked, and presents challenges to visualization methods that are as large as the potential benefits. Robust visualization can reveal elusive connections among sets of articles, such as many articles in a set of results citing a single item that is, itself, not in the results set. It might also be desirable for some users to navigate through a visual map of the citation space in a field or arrayed around the works

Fig. 4 Section of the Citation Report. Citation Report on the 8037 records retrieved using a topic search for “global warming.” The default ranking is in descending order by times cited to allow identification of the h-index core, i.e., the set of articles with a citation count greater than or equal to the value of the h-index. Data from Citation Report can be saved to a delimited file to allow customized analyses.

of an individual author. The irregular density and complexity of the citation network underlying the *Web of Science* makes this an ambitious goal. The Citation Map feature is an initial step, allowing references to be organized, color-coded, and in other ways, made to reveal patterns and trends.

Additional Features and Services

Additional features of the *Web of Science*, while enhancing the access to and manipulation of bibliographic records and data, are less directly related to the fundamental concept of a citation index and will be mentioned only briefly here. Record exporting has been made more accessible through a quick export. This allows users to bypass the Marked List to export records with a minimum, standard set of data elements or with a complete set of tagged data. Users also have access to the Web version of the popular bibliographic management tool, *EndNote* as part of the *ISI Web of Knowledge* platform, allowing them to store a library of references that is accessible via any computer. *ResearcherID* offers a new

way to develop, view, and manage the record of one's own publications, and uses the analytical tools from *Web of Science* to reveal patterns within the collection of articles that cite one's own work. An ever-improving set of customizations, alerts, saved searches, and personal journal lists in the *ISI Web of Knowledge* platform embed the information in the *Web of Science* within the ways scholars use information.

CONCLUSION

The 11 years since the first release of the *Web of Science* have seen sweeping changes in almost every aspect of scientific communication and publishing, as well as in the interrelated fields of library and information sciences, information management, retrieval, and use. As the needs and practices of researchers change, the functionality, content, and interface of the *Web of Science* continue to evolve, but the critical insight and immense usefulness of citation indexing and cited reference searching remain at the very heart of the product.

Abstract: There is now ample evidence of the ecological impacts of recent climate change, from polar terrestrial to tropical marine environments. The responses of both flora and fauna span an array of ecosystems and organizational hierarchies, from the species to the community levels. Despite continued uncertainty as to community and ecosystem trajectories under global change, our review exposes a coherent pattern of ecological change across systems. Although we are only at an early stage in the projected trends of global warming, ecological responses to recent climate change are already clearly visible.

Citer Motivations [ELIS Classic]

Terrence Brooks

iSchool, University of Washington, Seattle, Washington, U.S.A.

Abstract

Much informetric research is based on the analysis of the citations that authors make to the publications of other scholars and researchers, whose work they have used in their own articles and books. If such measures are to be useful for understanding scientific recognition and the ways in which scientific results build on earlier work, then an understanding of the motivations of the people doing the citing can be helpful in evaluating the validity of the research based on the citation analysis.

—*ELIS Classic*, from 1988

INTRODUCTION

Citations are one of the hallmarks of scholarly writing. They reside in one text, and point to other texts that the author wants to bring to the attention of his reader. Why would an author want to do that? The study of citer motives begins with this question.

Citations are examples of unobtrusive or nonreactive social science measures.^[1] Unobtrusive measures are physical evidences of activity that exist independently of their source: the private act of authorship produces citations that are public objects available for scrutiny and analysis. As with many of these unobtrusive measures, it is difficult to ascertain in any given application what social or psychological construct the citation counts are measuring.

Many people consider citations as positive evidences of scholarly opinions. In this view, heavily cited works enjoy the attention of scholars while uncited works suffer their neglect. This is a naive correlation of citation activity and scholarly opinion. It assumes that there are identifiable citer motives that govern the behavior of scholars. This article surveys attempts to catalog what those citer motives might be.

Citations have *prima facie* validity because it is plausible to consider them as measures of scholarly eminence, intellectual worth, or subject value. Many of the univariate models of citer motivations surveyed below portray a citation as a signal that the writer was influenced by the material cited. The *prima facie* validity of citation analysis is reinforced by several credible studies that report correlations among highly cited individuals and other measures of scientific achievement. Both Narin^[2] and Myers^[3] report strong correlations among frequently cited authors and other independent measures of eminence. Virgo found citation analysis to be a consistent and accurate predictor of important scientific papers; better on the average than the individual scientist's judgment which "is a reasonable conclusion if one considers that citations actually reflect a

consensus of a large group of readers as compared to the evaluation of a single individual" (p. 423).^[4]

When citations are considered as artifacts of the psychological state of an individual writer, they are less credible. There are many possible motives driving citation behavior that have nothing to do with scholarliness, intellectual worth, or subject value. Self-citation, collusive arrangements among researchers, and even universal condemnation among peers are examples. As Ravetz succinctly put it, "by appropriate nuance of mention, one can under-cite without actually stealing results, or overcite with the effect of inflating the value of the property of a colleague" (p. 257).^[5]

There have been two lines of attack on the validity of citation analysis; both involve citer motives. The first is that citer motives have not been studied empirically, and therefore exist only as objects of speculation. Thorne^[6] and Bavelas^[7] are vociferous critics of citation analysis who follow this tack. Advocates of citation analysis have responded to such criticisms by developing citer motivation models, each with a certain *prima facie* validity or special application. Many citer motives have been suggested from simple univariate models to complex multivariate taxonomies. These models are reviewed below.

The second line of attack on citation analysis was suggested by Martyn.^[8] He speculated that two or more citers may not be targeting the same informational unit in a mutually cited paper. Martyn broadly defined informational units as simple propositions, computer bits, or any other feasible unit. Consequently, linking two authors together based on shared citations may be spurious: each was targeting different informational units in the cited paper. While Martyn intended this caveat to pertain only to bibliographic coupling, he nevertheless added another dimension to the citer motivation problem. It appears to be quite possible that authors perceive cited papers as harboring several information units, and at the same time, they may employ complex motives in targeting those informational units. About a decade later, Small^[9] made

the contradictory observation that scholars regard cited papers as representing a single concept, which would be only one information unit as defined by Martyn. Furthermore, Small suggested that authors are uniformly motivated when they cite such a paper. He used content analysis to examine the text surrounding individual citations, and found textual regularities suggesting that certain works act as shared symbols. In his view, citations act as symbols of single concepts. This implies that many scholars share the same motives when they cite works that stand for shared symbols in their fields. Both lines of attack on citation analysis are unresolved at this time. As can be seen below, there are many candidate citer motivation taxonomies and the one, or several, most appropriate models have yet to be articulated. The Martyn/Small confrontation is similarly unresolved.

Content analysis^[10] has been the major tool used in deducing citer motivations. This approach quantitatively analyzes texts for signs, symbols, or messages. The validity of this approach, and therefore the validity of the resultant citer motivation taxonomies based on content analysis, is premised on a consistent classification procedure: different people should code the text in the same way. Consistent text coding is not easy, and few researchers who categorize citations are as candid as Stigler and Friedland about the pitfalls of using a content analytic approach:

Usually a citation is easy to classify. ... Often, however, the classification taxes one's casuistical skill. Consider Hicks's review article on Patinkin, which begins by stating: "The main things I have learned from [the book] are not what the author meant to teach me. ..." It is not complimentary to be told that one did not understand his own message; it is complimentary for an economist to be able to teach Sir John anything—so the passage is classified as neutral. Although there is no ambiguously correct classification, we believe the classification has been fairly consistent. (p. 489)^[11]

These comments illustrate several liabilities of the content analytic approach. Stigler and Friedland^[11] used a simple univariate citer motivation model with categories of "favorable," "unfavorable," and "neutral." The citation under examination did not easily fit into either "favorable" or "unfavorable," so they compromised and called it "neutral." This suggests that their results may be method bound. Several of the following models used in content analytic experiments also find a disconcertingly high percentage of neutral or perfunctory references. These results probably illustrate the limitations of the citation taxonomies employed. Stigler and Friedland^[11] were also struggling with an apparently mixed citation motive since they considered Hicks to be both complimentary and critical simultaneously. Many of the following models fail to recognize that authors may be motivated by a complex psychological state when they cite other works. Finally, it is worth speculating that much enlightenment about these matters might be gained by interviewing authors

themselves about their citation behavior. Historically, however, the approach of content analysis has been favored over any other. Given the problems inherent in a content analytic approach described above, future researchers may be prompted to try other, more fruitful approaches.

UNIVARIATE MODELS OF CITER MOTIVATIONS

A univariate model of citer motivations attempts to represent the psychological state of a citer along one dimension such as favorable-neutral-unfavorable. Many early citer motivation models are of such a simple nature. They can be roughly grouped into categories such as:

SCIENTISTS ALL ACT THE SAME

Price^[12] postulated an average conscientiousness, and Martino^[13] a scholarly custom of citer motivations. Many people agree with Whitley^[14] that scientists cite anything and everything they consider important.

RULES OF BIBLIOGRAPHY

Creager and Harmon^[15] suggested that the arduous task of compiling a list of references will tend to inhibit authors from including irrelevant citations. Kaplan^[16] felt that some rules of bibliography were passed informally from teacher to student.

NEED FOR CURRENCY

Both Bavelas^[7] and Line and Sandison^[17] suggested that scholars cite to show an awareness of the important work in their field, or to show up-to-dateness.

In the last decade, a new discipline, the social studies of science, has also produced several citer motivation models. These motives relate to a scientist's need to claim new intellectual territory,^[12] to recognize intellectual property rights,^[16] or to provide a form of "income" in terms of status.^[5] Gilbert^[18] considered citations as elements of the rhetoric of argumentation. He portrayed an author as struggling to present his best case to his reader, and as using references as tools of persuasion.

Citations have also aided sociologists and historians of science in tracing the development of intellectual models or paradigms. Fleck^[19] described the establishment and transmission of ideas within a scientific community, and categorized the active use of cited material as forming part of the "thought collective" of a group of scientists. The passive use of cited material denoted information less useful in a paradigm. Dolman and Bodewitz^[20] used

Fleck's active/passive categories to calibrate how papers have become accepted, or in their jargon, "sedimented." With the passage of time, the increasing number of active-type citations shows that an idea has become sedimented.

MULTIVARIATE MODELS OF CITER MOTIVATIONS

A number of researchers have offered complex multivariate taxonomies of citer motivations. Several have specific subject application.

GARFIELD'S TAXONOMY

Eugene Garfield^[21] commented on the difficulty of automatic indexing for several reasons including the many citer motives authors may use. He offered the following list of citer motives.

1. Paying homage to pioneers
2. Giving credit for related work (homage to peers)
3. Identifying methodology, equipment, etc.
4. Providing background reading
5. Correcting one's own work
6. Correcting the work of others
7. Criticizing previous work
8. Substantiating claims
9. Alerting readers to forthcoming work
10. Providing leads to poorly disseminated, poorly indexed, or uncited work
11. Authenticating data and classes of fact—physical constants, etc.
12. Identifying original publications in which an idea or concept was discussed
13. Identifying original publication or other work describing an eponymic concept or term (e.g., Hodgkin's disease, Pareto's law, Friedel-Crafts reaction, etc.)
14. Disclaiming work or ideas of others (negative claims)
15. Disputing priority claims of others (negative homage)

LIPETZ'S CITATION RELATIONSHIPS IN SCIENCE LITERATURE

Ben-Ami Lipetz^[22] sought to improve citation indexing by using codes to indicate the precise relationship of the citing work to the cited reference. His model was the legal citation indexes that provide information that a later case affirms, refutes, and so on, an earlier case. The following taxonomy was developed by examining articles in physics.

Group One. Original scientific contribution or intent of citing paper.

1. Description of observed phenomena
2. Data transformation
3. Explanation
4. Hypothesis or theory
5. Calculation from theory
6. Prediction
7. Definition or notation
8. Statement of experimental technique

Group Two. Contribution of citing paper other than original scientific contribution.

9. Review article
10. Bibliography
11. Data cumulation

Group Three. Identity or continuity relationship of citing paper to cited paper.

12. One or more authors in common
13. Same text
14. Abstract or condensation
15. Erratum
16. Continuation
17. Precursor
18. Inclusion

Group Four. Disposition of the scientific contribution of the cited paper in the citing paper.

19. Noted only
20. Distinguished
21. Reviewed or compared
22. Applied
23. Improved or modified
24. Replaced
25. Changed the precision (plus or minus)
26. Changed the scope of applicability (plus or minus)
27. Questioned
28. Affirmed
29. Refuted

HODGES'S TAXONOMY

Theodora Hodges^[23] evaluated the potential of citations indexing for bibliographical control, and produced the following elaborate taxonomy. The entries have been abbreviated here; her dissertation provides extensive discussion of each category.

Evidential references: Writings which are cited later in other writings as providing evidence for what those later writings are themselves contending. . .

Corroborative references: . . . A corroborative reference is to parallel rather than to sequentially related work.

General informational references: References made for the purpose of providing general information cast a very wide net. . . . The apparently dissimilar writings juxtaposed by having referred to the same work or works as general background information may contain a common element. . . .

Specific information references: . . . The class of writings they lead to is neither so wide nor so heterogeneous [as general informational references].

Historical references: . . . From a subset of either general or specific background references. . . .

Documentary references: . . . Those in which the documents referred to are of such specific content in themselves that works citing them are likely to have something in common. . . .

Sibling references: . . . The term “sibling” is attached to references which are to other pieces of the same series of experiments, experiments which should be of interest as a set simply because they were so planned.

Methodological references: Forward links from writing cited in explanation of the methods used are undoubtedly of interest to those working directly on whatever method is cited. . . .

Oppositional references: References which mention opposing explanations for the same observed phenomena as are explained in the citing paper are probably very important links to helpful writings.

Corrective references: There can be no doubt at all that references which point out work which is corrected are important as forward links.

Clarificational references: A clarificational reference helps an author delineate his position: he does not usually in the course of making such a reference, add anything to the exposition of the work he is using.

Logical references: The relationship of a paper to that or those which it cites as logically antecedent to itself is thus very close, so close that a man interested in a paper cannot afford not to know how its implications are further developed. . . .

Expositional references: Most people interested in a given work are concerned with understanding it, and can be expected to find works devoted to furthering the general understanding of that work helpful.

Illustrative references: Illustrative references are seldom of any more than rhetorical importance in the development of the ideas in any one: they serve the same function, though at a more superficial level, as clarificational references.

PERITZ'S SOCIAL SCIENCE TAXONOMY

Bluma Peritz^[24] streamlined Hodge's unwieldy taxonomy down to eight categories, and applied it to five social

science journals. Peritz also noted how her categories related to those of Hodges's.

Setting the stage for the present study. . . Citations to previous work which leads up to the research questions asked in the present investigation. Hodges calls this group “evidential.”

Background information. . . Citations which document basic data. . . or support factual information. . . . Hodges distinguishes between general and specific information but this distinction did not seem to be workable, or relevant, in practice.

Methodological. . . Citations describing some aspect of the methods used. . . .

Comparative. . . Citations to other studies with which the present one is being compared. (Hodges speaks about “corroborative” citations; some of her “oppositional” and “corrective” citations, would also fit into this category.)

Argumental, speculative, hypothetical. . . Citations made in supporting the formulation of new hypotheses and conjectures. . . No such category appears in Hodges's classification.

Documentary. . . Citations which refer to the sources of raw data. . . . This category includes also most of what Hodges calls “sibling” citations. . . .

Historical. . . citations made while retracing the history of the subject. . . .

Casual. . . Citations not directly tied to the issue at hand. . . .

Peritz reported enthusiasm for the content analytic approach. Her comments reflected unintentionally on the Martyn/Small controversy (p. 308).^[24]

The classifying procedure itself is easy to carry out, even without in-depth knowledge of the field; a general understanding of the paper's main message is sufficient. In most cases the text surrounding the citation provides unequivocal clues for its classification.

FROST'S CITATION CLASSIFICATION FOR LITERARY RESEARCH

Carolyn Frost^[25] proposed the following taxonomy for literary research. She applied it to a small sample of works in German literature.

- A. Documentation of primary sources—references to literary texts, letters, etc.
 1. To support an opinion or factual statement on the specific literary author(s) discussed in the citing work;
 2. To support an opinion outside the central topic of the citing work; or
 3. To support a factual statement outside the central topic of the citing work.

- B. Documentation of secondary sources—references to previous scholarship.
1. Independent of approval or disapproval of the citing author.
 - a. To acknowledge the pioneering work of other scholars;
 - b. To indicate the state of present research, a range of opinions, or prevailing views on a topic; or
 - c. To discuss the meaning of a term or refer to a work in which a given term or symbol first appears.
 2. Representing the approval of the cited scholar.
 - a. To support an opinion of the citing author;
 - b. To support a factual statement of the citing author;
 - c. To take an idea a step further; or
 - d. To acknowledge intellectual indebtedness.
 3. Representing the disapproval of the citing author.
 - a. To disagree with an opinion of the cited author;
 - b. To disagree with a factual statement of the cited scholar; or
 - c. By expressing a mixed opinion.
- C. Documentation of sources either primary or secondary.
1. To refer to further reading; or
 2. To provide bibliographic information on a specific edition.

CITATION CATEGORIES OF MORAVCSIK AND MURUGESAN

This multivariate citer motivation taxonomy was refined by Moravcsik and Murugesan^[26] in a series of papers, and represents a model from the social studies of science field.

Conceptual references: If a concept or theory of the cited paper is used directly or indirectly in the citing paper in order to lay foundations to build on it or to contribute to the citing paper, then the citation is a conceptual one.

Operational references: When a concept or theory is referred to as a tool. . .[or] when it borrows mathematical or physical techniques, results, references, or conclusions from the cited paper.

Organic references: . . . Those [papers] from which concepts or theories are taken to lay the foundations of the citing paper, or papers from which certain results (including numerical ones) are taken to develop the ideas in the citing paper, or papers which help to better understand certain concepts in the citing paper.

Perfunctory references: . . . Those [papers] which describe alternative approaches are not utilized in the citing paper. . . references which are used to indicate the fact that a certain method employed is routine in the literature, and references which merely contribute to the chronological context of the citing paper.

Evolutionary references: . . . [The paper] provides a concept or theory to build on, or a mathematical technique to use, or results of an analysis which is used in the development of the citing paper, or notation used in the citing paper.

Juxtapositional references: . . . [The paper] refers to alternative approaches. . . [and] refers to other analysis used in the citing paper only to make comparisons, refers to other works which may help to clarify some ideas but do not contribute to the development of the citing paper, or refers to a paper only for references given in the latter.

Confirmative references: A reference is confirmative if the author of the citing paper considers the paper referred to as correct.

Negational references: . . . The author of the citing paper is not certain about the correctness of the cited paper.

This has been an influential taxonomy. Dolman and Bodewitz^[20] compared their active and passive categories to the conceptual and operational categories listed above, and Ruff^[27] used the perfunctory and organic categories to analyze papers citing the life work of Istvan Kovacs, a theoretical molecular spectroscopist. It also directly influenced the work of Chubin and Moitra.

CITATION CATEGORIES OF CHUBIN AND MOITRA

This taxonomy also originates in the social studies of science. Chubin and Moitra^[28] were unhappy with the high percentage of perfunctory references reported by Moravcsik and Murugesan, and wished to redefine their taxonomy into mutually exclusive categories.

Affirmative Citations

Essential Citations

Basic citations. If the referenced paper is declared central to the reported research. . .

Subsidiary citations. If a specific method, tool, or mathematical result is not directly connected to the subject of the paper. . .

Supplementary Citations

Additional citations. When the referenced paper contains an independent supportive observation (idea or finding). . .

Perfunctory. . . . Papers referred to as related to the reported research without additional comment.

Negational Citations

Partial. . . This paper is erroneous in part. . .

Total. . . The paper is completely wrong. . .

VALIDATION OF CITER MOTIVATION MODELS

Little work has been done toward validating the citer motivation taxonomies enumerated above. One reason has been the lack of rationalization of the numerous categories that overlap, or leave gaps, in the multivariate

taxonomies. A second reason is that certain taxonomies may be more appropriately applied in certain subject fields than others. Both of these problems present large challenges to future researchers.

Brooks^[29] attempted a general rationalization of the citer motivation models presented above with the following categories: currency, negative credit, operational information, persuasiveness, positive credit, reader alert, and social consensus. He interviewed 26 authors who assessed each reference they gave in a recently published paper, and described their motives by using one or more of these scales. Persuasiveness was one of the most popular motives.

In a follow-up study, Brooks^[30] explored complex interactions among these seven motives, and found they could be reduced to five: (1) persuasiveness; (2) negative credit; (3) currency, positive credit, and social consensus; (4) reader alert; and (5) operational information. A finer analysis of positive and negative citations showed they were often correlated. In other words, when an author gave a negative reference, he often associated it with a countervailing positive credit, currency, or social consensus reference. Brooks considered this to be empirical evidence of the hypothesis of MacRoberts and MacRoberts^[31] that scholars dissemble when giving negative references.

CITATION CONTEXT ANALYSIS

Small's contention that citations are concept symbols is an area of active research interest. There is the possibility that advances in related fields such as rhetoric and semiotics will contribute tools to analyze the conceptual use of citations. Concept analysis has firm philosophical support from the study of science:

Cognition is the most socially conditioned activity of man, and knowledge is the paramount social creation. The very structure of language presents a compelling philosophy characteristic of that community, and even a single word can represent a complex theory. . . . This social character inherent in the very nature of scientific activity is not without its substantive consequences. Words which formerly were simple terms become slogans; sentences which once were simple statements become calls to battle. This completely alters their socio-cognitive value. They no longer influence the mind through their logical meaning—indeed, they often act against it—but rather they acquire a magical power and exert a mental influence simply by being used. . . . Whenever such a term is found in a scientific text, it is not examined logically, but immediately makes either enemies or friends. (p. 42)^[19]

Small^[9] found that all of the mostly highly cited papers in chemistry were used uniformly, as based on his content analysis of their textual settings. For example, one of these, the most highly cited paper in all of science:

Lowry, O.H.; Rosebrough, N.J.; Farr, A.L.; and Randall, R.J. Protein Measurement with the Folin phenol reagent, *J. Biol. Chem.* 193: 265, 1951.

was used in all cases to refer to a certain protein determination method. Small concluded that scholars who cite Lowry et al. in their text were placing a commonly understood symbol that other scholars would immediately recognize as the concept of protein determination. In this way scholars share concepts, and use citations to represent those concepts.

Two recent developments have complicated the relationship between a citation and its conceptual use. For example, a citation's conceptual meaning may change with time. Small^[32] found a paper that in its early history was symbolic of a unique collagen type. Later, after contradictory evidence emerged, its symbolic function changed to that of a controversial hypothesis. This implies that the conceptual use of a citation may evolve throughout its lifetime. Cozens^[33] introduced a further complication that the same citation can have more than one conceptual meaning at any given time. She found that two different groups of scholars were referring to the same paper—in each case treating the paper as the symbol of one concept—but the groups did not agree as to which symbol the paper represented. She called this phenomenon a split citation identity.

CONCLUSION

This survey has illustrated that to inquire why authors give citations is to pose a complex question that cannot be answered satisfactorily at this time. Univariate models of citer motivations lack credibility, and multivariate models suffer a lack of coordination in scope and purpose. Major future challenges to researchers in this field are to rationalize the multivariate citer motivations taxonomies, and to develop the study of the conceptual use of citations. Advances in both of these areas will probably require the application of social science methodologies other than content analysis.

Classification Theory

Clare Beghtol

Faculty of Information Studies, University of Toronto, Toronto, Ontario, Canada

Abstract

In the library and information sciences, classification theories are used primarily for knowledge organization, either in a manual or in a machine environment. In this context, classification theories have usually been developed initially as a support for specific knowledge organization classification systems, although the theories and the systems have influenced and re-influenced each other in particular ways throughout their lives. This entry discusses theories for knowledge organization classifications using examples from a number of classification systems, but no one system is discussed at length. Instead, the entry is organized into sections that deal first with classificatory issues in general and then with theories of content, theories of structure, and theories of notation for knowledge organization classifications.

INTRODUCTION

Theories of how knowledge organization classifications should be created, developed, structured, used, and communicated to others underlie the systems themselves. To classify means to put things into meaningful groups. Things can be physical objects, ideas, events, or anything else that human beings can perceive or imagine, and a meaningful group can be formed using any characteristic or combination of characteristics of the things. Groups can be considered to be permanent or they can be considered temporary responses to a need of the moment. These groups of things can then be combined and arranged to make a knowledge organization classification system. A knowledge organization classification is a structured plan that ideally shows all the groups that have been created and their relationship(s) to each other.

GENERAL ISSUES IN CLASSIFICATION

Knowledge organization classification theories and the systems they give rise to are cultural artifacts that directly reflect the cultural concerns and contexts in which they are developed. This cultural dependence means that no knowledge organization theory or system can be useful for every time and in every place because knowledge organization theories and systems for one time and place will be unsuitable or irrelevant for another. For example, different countries have different educational systems, and a knowledge organization classification for education in one country is not helpful for education in another country. The same constraint applies to different times in the same place—education in the nineteenth century was very different from education in the twenty-first century. This cultural component in classifications of all kinds also means that each knowledge organization classification

will need adjustments in order to accommodate both new content and also the diverse ways human beings have devised to record and to communicate information and knowledge. For example, the modern phenomenon of electronic information technology has meant, among other things, that the existence of the new tools, the characteristics of electronic retrieval, and the kinds of electronic information objects computers can make available have had to be accommodated by knowledge organization classification theories and systems.

It follows, too, that the study of knowledge organization classification theories and systems is transdisciplinary. Classificatory issues are important intellectual components of every field, and classification literatures can be found in databases and other finding aids for every topic or field of study. For example, classification is an important activity in biology and other scientific fields, statistics and other mathematical areas, sociology and other social science areas, and music and other arts and humanities areas. Numerous publications exist on classificatory issues in every field. For example, Vickery^[1] provided Appendix A, “Historical Aspects of the Classification of Science” (pp. 147–180), which includes some representative classifications of science (pp. 174–180). Veltman^[2] examined knowledge organization in the visual arts. Douglas and Hull^[3] and Ellen and Reason^[4] provide essays on a wide variety of classification topics in the social sciences. Classificatory activities in all fields are driven by the theories that are appropriate for that purpose, topic, time, and/or place.

Groups of things can have many different purposes, and a knowledge organization classification may contain groups of things that may not seem intuitively related to each other. For example, suppose we grouped together a painter’s easel, a cow, a lunar landing pod, and the map of a journey we plan to take. All those things have “legs,” either literally or figuratively. This group could belong in

a knowledge organization system the purpose of which was to gather and organize the literal and figurative meanings of words relating to the human body. It would not, however, belong in a knowledge organization classification the purpose of which was to group objects that have been created by human beings because a cow is not a human creation. It follows that creating a group or class for one purpose entails omitting things that do not fit into that class. Classifying thus simultaneously creates two major groups: 1) a group of things that all belong to a particular larger group and 2) another group of things that do not belong to that larger group. Normally, the group of things that are omitted is larger than the group of things that are included because the omitted group includes everything in the world that does not belong in the included group (e.g., the group of all things that do not have legs).

For human beings, classifying is a cognitive imperative; infants begin to group things as soon as they are born. Perhaps the most basic tool we use for grouping is natural language, either spoken or written. A natural language is a language that has evolved over time and that people use in their daily lives. If we say something is a “chair,” that word gathers all the things that could be called chairs and omits from that group all the things that could not be called chairs. A number of complications arise from natural language, however. One complication is that words can be used both literally and figuratively as in the example of things with legs given above, and another complication is that each group needs to have a name or a label that describes what belongs in the group. Thus, the problems of language recur throughout all the levels of every classification system.

This discussion implies that one result of creating a knowledge organization classification system is to provide a context in which to understand the intended meaning of a particular word. By saying that a cow belongs to a group of things that have legs helps us to understand which of the possible meanings of the words cow and leg is intended. Other implications are that the relationship(s) of all the things in the knowledge organization classification needs to be shown in some way in the groups and in their names, that the relationship(s) among the groups themselves will need a name, and that the knowledge organization classification itself will need to have an appropriate inclusive name. Knowledge organization systems for the whole world of knowledge are called general or universal knowledge organization systems, and knowledge organization systems for a smaller part of the world of knowledge (e.g., astrophysics) are usually called special classifications.

Traditionally, the groups in a classification system should be “mutually exclusive” and “jointly exhaustive.” The criterion of mutual exclusivity applies throughout the classification system. It means: 1) that a certain named thing should occur in only one class and 2) that the class

in which the thing occurs should have no overlapping content within itself. The criterion of joint exhaustivity means that each class in the classification system and the entire classification itself should contain all and only those things that are appropriate to the classes and to the entire system. Nothing relevant should be omitted, and nothing irrelevant should be included. Taken together, mutual exclusivity and joint exhaustivity mean that the classification system should contain all and only the appropriate things for each class and for the classification as a whole, and that there should be no overlap of content among the various classes.

These criteria create a number of problems, especially when they are considered in relation to the problems of natural languages. It is probable that no knowledge organization classification system completely meets both criteria. Suppose we have a knowledge organization classification for “physical objects that people have created.” One major class in this system might be called Furniture and another major class might be called Vehicles. One of the requirements of the criterion of mutual exclusivity is that only kinds of furniture should be in Furniture and only kinds of vehicles should be in Vehicles. The problem then arises of things people have created that could legitimately belong to either major class. Where should a wheelchair or a baby’s stroller be placed? These objects belong in the classification system because they have been created by human beings, but both of them function both as furniture and as vehicles. On the criterion of joint exhaustivity we can also anticipate problems. What will happen when a new kind of furniture or a new kind of vehicle is invented? Before airplanes were invented, we had no name for this kind of vehicle, and it could not have been included in a knowledge organization classification for objects people have created. Yet, as soon as machines that could fly were invented, a knowledge organization classification for things that people have created that did not include these flying machines was immediately out of date. For this reason, knowledge organization classifications need to be updated regularly. The ability to include new things in the appropriate place in a knowledge organization classification is called hospitality.

Organizations

The International Society of Knowledge Organization (ISKO) (<http://www.isko.org/>) has active chapters in Asia (China and India), Europe (France, Germany, Austria and Switzerland, Italy, Poland, Spain, and the United Kingdom), and North America and South America. International conferences are held every two years, and these conference proceedings are published. ISKO’s official quarterly journal is *Knowledge Organization*. The Special Interest Group for Classification Research (SIG/CR) of the American Society for Information Science and Technology (ASIST) holds a yearly workshop during the annual

conference of its parent organization (<http://www.asis.org/SIG/cr.html>). Regional chapters have been formed in the continental United States and Taipei. The proceedings of the yearly workshops are published as *Advances in Classification Research*. These two organizations deal with classificatory activities and debates in all fields and are two of the major sources of information about classificatory issues.

Terminology

In this field, the same term can be used in different ways. For example, the person who creates a classification system is a “classificationist” or a “classifier,” but “classifier” can also be used for the person who applies an existing knowledge organization classification. “Classed” or “classified” can be used interchangeably, as in “classed catalog” or “classified catalog.” These differences mirror preferences in the culture or discipline of the writer.

“Theory” as used in this field is not testable or replicable in the strict scientific sense. These theories are not subject, for example, to double blind experiments or similar kinds of empirical validation. The theories presented here are not susceptible to statements of truth or falsity. Instead, writers on classification consider a certain theory better or worse, more useful or less useful, than other theories for various reasons. Theories necessarily contain assumptions and discussions about what would be better or worse in a particular situation, and they attempt to establish classificatory principles that will achieve better results than other possible principles would achieve. These issues in relation to classificatory cognition and behavior are discussed in Lange.^[5] Often, classification theorists combine their own theories and principles with those of others, either consciously or unconsciously.

“Document” is a generic term for a container of information objects. The container can be in any form or format, for example, in a book, on a Web page, in an architectural drawing, from a piece of music, or in any other way in which people record information and knowledge in order to remember it and to communicate it to others. This inclusive perspective on recorded knowledge allows us to reveal the pervasiveness of classification in human life, language, and culture. It generalizes discussions of theories and issues in knowledge organization classification and other kinds of information work in order to emphasize they are not restricted to one medium of information exchange.

“Warrant” is a term that in this field means the justification and rationale for important types of decisions about a knowledge organization classification theory and the systems to which it gives rise. For example, the cultural dependence of a knowledge organization classification is called its cultural warrant. In the knowledge organization literature, a number of kinds of warrant have been identified, such as literary warrant, user warrant, institutional warrant, and ethical warrant. The different kinds of warrant

individually or in combination seek to provide a consistent theoretical foundation for decision-making about the various elements of a knowledge organization classification.

Scope and Perspective

Given the ubiquity and importance of classificatory activities in human language and interaction, it is important to set out the scope of any discussion of classification theory. This entry deals primarily with bibliographic library knowledge organization classification theories and their assumptions, principles, and elements. Bibliographic library knowledge organization classification theories and systems have been developed for whole documents, not for parts of documents. Historically, these kinds of classifications were developed as knowledge organization classifications for collections of books in libraries and were primarily used for shelving and in some cases for catalog arrangement in specific library catalogs, union catalogs, or bibliographies. The knowledge organization classification theories developed for these purposes were often used as the basis for particular classification systems and were adapted and modified by other theorists for their own purposes. At the same time, other accessing methods, such as indexing (see also Indexing), addressed the content of parts of documents. In cases of both whole and partial document accessing methods, the original theories assumed manual, nonelectronic accessing capabilities. More recently, both bibliographic library knowledge organization classifications and indexing theories and methods are being adapted for electronic purposes in information retrieval applications, both for whole documents and for parts of documents, and other theories are being developed solely for electronic media. Thus, to obtain a complete view of issues of document analysis and access over time, this entry should be read in conjunction with related entries in *ELIS*, including those on specific classificationists and on specific systems (see also the Table of Contents).

Structure of This Entry

After this introduction, the entry is organized in six parts. First, three theoretical planes of work for knowledge organization classification are identified. Next, background and foundations for current knowledge organization theories and systems in the library and information sciences are briefly described. Using the three planes of work previously identified, theories of: 1) how to decide on the appropriate sources for the content of a knowledge organization classification system; 2) how to structure knowledge organization systems; and 3) how and what kind of notations to provide for the systems are discussed. Like all systems of organization, the one adopted for this entry is artificial, the boundaries between the concepts are not rigid, and the issues that arise are not mutually exclusive.

For that reason, a final section bringing together all the theories is provided.

BIBLIOGRAPHIC LIBRARY KNOWLEDGE ORGANIZATION CLASSIFICATION

Three Theoretical Planes of Work

S.R. Ranganathan suggested that classificatory work could be divided into three planes: the idea plane, the verbal plane, and the notational plane. Each of these elements has been theoretically examined and developed extensively in the literature. The idea plane is the conceptual basis for a knowledge organization classification system, including appropriate considerations of its purpose, its warrant, its content and its structure. The idea plane deals with the foundations of knowledge organization and theoretically governs all the decisions that go into the development of a knowledge organization classification.

The verbal plane comprises the words that are used to describe concepts in the schedules of a knowledge organization classification. The verbal plane instantiates the principles of the idea plane and helps to express and demonstrate the relationship(s) between and among concepts in the knowledge organization classification. If the system has an alphabetic index, the verbal plane provides complementary access to the schedules using terms from the schedules and synonyms for them that might be looked up by a user trying to find the place for a topic in the schedules. Two kinds of indexes for this purpose are the relative index, invented by Melvil Dewey, and the chain index, invented by S.R. Ranganathan.

The notational plane requires decisions to be made about the coding that stands for the place of the concepts in the system. Once the sources of content and the structural principles have been chosen for a classification system, a notation is usually provided for helping to identify the order in which documents have been organized by the knowledge organization classification. Notation is a code that stands in place of the name of a class and ideally facilitates use of the classification: 1) by demonstrating the position of the class in the system and 2) by showing the relationship(s) of the class to other classes. A notation is assigned to each class and subclass in the system, and the documents in these classes are then uniquely identified by their separate notations. Notation can be visible to the information seeker, as in a library where users can browse open stacks using the notation to find materials that have the same general topic and that are physically located near each other. Alternatively, notation can be invisible to the information seeker, but still used to organize information for display in an electronic environment (e.g., on a Web page or in an electronic library catalog). A number of different kinds of notation have been developed based on different principles (e.g., expressive, faceted, retroactive),

and the characteristics of each kind are considered when choosing one for a particular classification system.

Background and Foundations

In the library and information sciences, knowledge organization classification theories and the systems that have been based on them have a long history. Usually, Aristotle (384–322 BCE) and Sir Francis Bacon (1561–1626) are credited with being among the historically important figures who have influenced knowledge organization classification theory in library and information sciences fields, but modern authors have more directly shaped the theories and systems we use today. For example, Melvil Dewey (1851–1931), Henry Evelyn Bliss (1870–1955), James Duff Brown (1862–1914), Paul Otlet (1868–1944), Henri La Fontaine (1854–1943), Charles Martel (1869–1945), and Shiyali Ramamrita Ranganathan (1892–1972) have all been influential. In this field, classification is also known as taxonomy or ontology, although with somewhat different meanings (see also Taxonomy and Ontology). In general, the purpose of library and information sciences knowledge organization classification systems is to organize recorded knowledge so that it can be accessed and acquired for use. Two kinds of these knowledge organization systems are usually recognized: general systems for organizing and accessing documents for the whole world of recorded knowledge and special systems for organizing and accessing documents for a particular area of recorded knowledge (e.g., biology or information studies). Knowledge organization classification systems, then, are tools initially for organizing and subsequently for retrieving information and knowledge for any kind of purpose in any kind of information container. Knowledge organization classification theories provide the conceptual bases of the systems and help govern which concepts are included and what principles of organization manifest themselves in the systems.

The foundations of most current knowledge organization classification theories and systems were established in the late nineteenth century. The *Dewey Decimal Classification* (DDC), the *Subject Classification* (SC), the *Universal Decimal Classification* (UDC), and the *Library of Congress Classification* (LCC) as well as less influential systems (e.g., the *Expansive Classification* (EC)) were all initiated before the beginning of the twentieth century. Further, two of the most influential classificationists, Henry Evelyn Bliss, who created the *Bibliographic Classification* (BC), and S.R. Ranganathan, who created the *Colon Classification* (CC), were born and began their education during the nineteenth century. Dates for the first editions of these systems were: DDC, 1876, Melvil Dewey; SC, James Duff Brown, 1908; UDC, Paul Otlet and Henri La Fontaine, 1899; LCC, Charles Martel, 1898; EC, Charles Ammi Cutter, 1891. Later, BC, Henry Evelyn Bliss 1940; CC, S.R. Ranganathan, 1933.

Except for UDC and LCC, each of these systems began as a library classification for open stack libraries where library users were able to browse the shelves, and each, including UDC and LCC, added to the store of knowledge organization classification theories, classificatory devices, and common practices for bibliographic classification systems. The foundation of these systems in nineteenth century thought has greatly influenced their development, but the evolution of these knowledge organization theories and systems has been neither entirely cumulative nor entirely linear. Instead, each has tried to address various theoretical and practical issues that arise in creating, maintaining, and using knowledge organization classification systems, initially in libraries that collected physical objects and now also including venues that collect virtual objects.

Originally, knowledge organization classifications were enumerative and precoordinated. An enumerative classification is one in which all the classes are decided upon in advance and are then arranged in an appropriate overall order. In an enumerative knowledge organization classification, all of the classes and subclasses of the system were enumerated in the printed schedules that ideally showed both the classes themselves and their relationship(s) to other classes. An enumerative knowledge organization classification is difficult to keep up to date because the pace of knowledge creation and change means they must be continually expanded to accommodate new concepts and ideas. At the same time, however, a knowledge organization classification must in addition continue to accommodate concepts that are of historical interest, although not currently considered valid. For example, chemists no longer study alchemy, but the literatures of alchemy from earlier times must still be enumerated in the schedules because scholars continue to study them. Similarly, many of the early knowledge organization classifications have now expanded their frames of reference and are applying their theories and principles to the wider realm of knowledge organization classification as retrieval devices for electronic information objects.

These kinds of systems are also precoordinated. That is, the document is analyzed to determine its “aboutness,” the result of that analysis is translated into the notation of the classification system, and document retrieval takes place using the notation for the document. The overall purpose of these systems is to help people find information that they can use for whatever purpose they had in seeking it. In a precoordinated knowledge organization classification, searching must be carried out in the order of the classes in the classification. For example, if we enumerate four classes for cats and give these classes a notation

Acats
ABcats—kinds
ABC cats—kinds—domestic
ABD cats—kinds—wild

we must then search for wild cats using the notational sequence ABD for cats—kinds—wild, and not a notational sequence AD for cats—wild because the notation AD will have a different meaning. Currently, we have replaced the theory of enumerative classifications with the theory of faceted classifications in which all the classes do not have to be enumerated in detail at the time of the creation of the classification. Similarly, the theory of precoordinated searching has been replaced with post-coordinated searching in which notational elements can be combined at will at the time of the search electronically. Discussions of these evolutionary changes appear throughout this entry.

Theories for the Basis of Knowledge Organization Classification Systems

Three major theories have emerged to describe the best place to start in creating a knowledge organization system: 1) the theory of literary warrant; 2) the theory of scientific and educational consensus; and 3) the theory of phenomenon based knowledge organization classifications. These theories deal with issues of where the sources for the content of a knowledge organization classification should be found. The theories themselves are not mutually exclusive, and elements from more than one theory can be seen in different knowledge organization systems. In addition, it is necessary to remember that the various theories were used to create knowledge organization systems. It is not useful or appropriate to divorce the theories from the knowledge organization classifications they were used to create.

The theory of literary warrant

The theory of literary warrant was developed by English librarian E.W. Hulme in his 1911–1912 essay “Principles of Book Classification.” He wrote that the name of a class should rest upon a

purely literary warrant. . . . A class heading is warranted only when a literature in book form has been shown to exist, and the test of the validity of a heading is the degree of accuracy with which it describes the area of subject-matter common to the class.^[6]

Here, Hulme implied that we need to classify existing books, not the more numerous potential books that could be written. In this, he relied on his view that putting things (books) in groups (classes) does not imply anything about how these groups should be arranged. He rejected the idea that the arrangement of the groups should be based on philosophical theories about the order of nature or the order of science. Instead, for Hulme, the purpose of book arrangements was to expedite locating the literature of interest, and the arrangement of groups

of books should be based on the contemporaneous common understanding of where books could be found. Classification in Hulme's view was not designed to educate library users, but to help them find books that they wanted to read.

Two conclusions followed from these views. First, Hulme suggested that each library would probably need its own classification system, just as each library had its own collection of holdings. The holdings in a particular library reflected the needs and interests of its users, who presumably supported the collection policies of the library, and their needs and interests should, therefore, drive the arrangement of the groups of books, both on the shelf and in the catalog. To Hulme, then, debates about classification did not entail debates about whether or not a classified arrangement was better or worse than an alphabetical one. By divorcing ideas about which groups to form from ideas about which arrangement of the groups to use, Hulme rejected theories of knowledge organization classification that relied upon philosophical or scientific theories about how knowledge should be arranged. Instead, Hulme espoused basing the knowledge organization classification upon the actual books the library had acquired or was likely to acquire in the future.

Second, Hulme demonstrated that, by examining the actual number of documents that were produced during different eras, we would be able to follow changes that had taken place in the development of what he called "civilization." The number of documents in each group would, Hulme believed, show the extent of the literature that existed in that knowledge area in that time and in that place, and, in consequence, show what people in that era were interested in. For example, using statistics of patented inventions and their applications in England between 1449 and 1921, he charted the course of the Industrial Revolution.^[7] This kind of statistical method of using bibliographic output as a way to understanding an age was the beginning of the development of what is now called bibliometrics.^[8]

Hulme's ideas were confined to classification of books in libraries because at the time he wrote books were the most prevalent library collections. Subsequently, a number of different kinds of warrant have been identified (e.g., terminological warrant, institutional warrant, user warrant, cultural warrant), and the theory of literary warrant has been extended to include these different warrants as foundations for grouping documents by means of knowledge organization classification systems. Similarly, during the twentieth century, libraries collected many kinds of documents other than books, and the theory of literary warrant was expanded to include those other kinds of documents (e.g., video recordings, music recordings, journals, research reports).

It is usually thought that development of LCC was based on the idea of literary warrant, even though Hulme did not publish his "Principles" until after the beginning of

LCC in 1898. Nevertheless, the idea that the rationale for a knowledge organization classification system resides chiefly in the content of the materials it seeks to describe is still an influential and useful theory. Regardless of any other rationale that is put forward, a warrant in what is being classified is fundamental. Clearly, if the purpose of the knowledge organization classification is to organize architectural drawings, the characteristics of the architectural drawings to be classified must be taken into account. In that case, the system would be based on "architectural drawing warrant." Further, it is clear that any system can have more than one warrant. All classification systems are embedded in cultural warrant and they can each have other kinds of warrants too.^[9,10]

The theory of scientific and educational consensus

The theory of scientific and educational consensus was put forward by H.E. Bliss initially in a 1910 essay "A Modern Classification for Libraries with Simple Notation, Mnemonics and Alternatives" and later in *The Organization of Knowledge and The System of the Sciences* (1929) and in *The Organization of Knowledge and the Subject-Approach to Books* (1933). He also summarized his ideas briefly in an essay "The System of the Sciences and the Organization of Knowledge" (1935).^[11-14] Bliss' idea was that a classification system should be based primarily on what he called the "scientific and educational consensus." He maintained that bibliographic knowledge organization classifications

should be organized in consistency with the *scientific and educational consensus*, which is *relatively stable* and tends to become more so as theory and system become more definitely established in general and increasingly in detail^[15]

To Bliss, the term "science," which is derived from the Latin "scientia," meant "knowledge in general." He believed that, over time, human beings would grow toward increasing agreement about the answers to fundamental questions that were asked not only in science but also in every other area of human enquiry (e.g., religion, aesthetics, and sociology). Further, he believed that this increasing consensus was mirrored in the way educational institutions organized themselves to pass recorded knowledge to future generations efficiently and effectively. The implication of the consensus idea was that classification systems for knowledge organization should be based on the consensual foundations that knowledgeable people used to organize their own studies and those of the educational institutions they established. Bliss gleaned and justified his ideas through his extensive and widely admired scholarly and theoretical studies of the philosophy of science,^[16] and he summarized his conclusions in five synoptic tables that showed the correspondences

between The Order of Nature, The Developmental Order of Knowledge, The Pedagogic Order, Logical Order, and [Order] by Speciality.^[17]

According to Bliss, only this consensual kind of knowledge organization classification would be appropriate for libraries because they collected materials that people would require for their studies in every area. He believed that expert advice on this consensus would assist the classificationist in developing an appropriate way of classifying every area of recorded knowledge, but he also understood that consensus was not yet complete. For that reason, he believed that a knowledge organization classification should provide alternative placements for topics about which there was still some level of disagreement or for libraries that needed to collect a particular group of documents in one place rather than scattering them throughout the classification. Bliss believed that alternative locations of topics within a knowledge organization classification were necessary in order to provide for the variety of purposes and interests that library patrons brought to their researches. The correlation of these views with the theory of scientific and educational consensus required that another principle, that of maximal efficiency, be added to the theory of consensus. Maximal efficiency meant that a knowledge organization classification should be designed so that both those who agreed with the common consensus and those who did not would find their views and/or purposes reflected in the schedules of the classification, depending on the library that was using the system. In turn, the search for maximal efficiency required two other principles to be established, those of subordination and collocation.^[18] These two structural principles are discussed below in the section on theories of structure for knowledge organization classification.

Bliss' contribution to theories of knowledge organization classification was highly influential for later theorists, but the first edition of his BC was not widely used or particularly well-regarded in the United States. Nevertheless, BC was the basis for the second edition (BC2) which is now considered the most theoretically advanced knowledge organization classification. Bliss' work has been related to the later work of Ranganathan on facet theory and facet analysis,^[19] and his various principles can also be usefully compared and contrasted with Ranganathan's Five Laws of Library Science (see also S.R. Ranganathan).

The theory of phenomenon-based knowledge organization

The theories of literary warrant and consensus were recognized as important and potentially influential when they were first enunciated, but phenomenon-based knowledge organization classification was little known when it was first developed and is only now gaining some prominence. Literary warrant and consensus both implied that the world

of recorded knowledge should be initially subdivided roughly on the prevailing academic disciplines, which are also sometimes called "forms" of knowledge (e.g., science, humanities, and social sciences). DDC, UDC, LCC, and BC first subdivided the world of knowledge along those lines, but the theory of phenomenon-based classification did not require an initial subdivision by academic disciplines or by the forms of knowledge.

The theory of phenomenon-based knowledge organization classification was enunciated and attempted by James Duff Brown, who developed what he called a "one-place" classification system in SC. Brown initially subdivided SC into five main groups: generalia, matter and force, life, mind, and record. The subdivisions of these main classes correspond somewhat to the forms of knowledge as instantiated in the academic disciplines, but Brown believed

there is not the slightest difficulty in working out a complete scheme from any basis, nor does it matter much into what main divisions specific subjects are put, provided always they are kept together on the shelves.^[20]

He did not, then, subscribe whole-heartedly to either the theory of literary warrant or to the theory of consensus. Instead, Brown believed that literature on "concrete" subjects (which he did not define) should be kept together on the shelves so that library patrons could find materials of interest at the same place. Using the example of the Rose, he wrote that the Rose could be treated from many different standpoints such as

Biological, Botanical, Horticultural, Historical, Geographic, Ethical, Decorative, Legal, Emblematical, Bibliographical, Poetical, Musical, Sociological, and so on to any extent.^[21]

In SC, Rose would be at one place in the classification, qualified by these various standpoints from which the subject Rose could be viewed. In that way, people interested in all aspects of the Rose would find all the literature on the Rose together because, using the special devices of SC's notation, all the books on the Rose would be gathered together on the shelves. Brown thus provided the theoretical rationale and a practical example for discussion of phenomenon-based knowledge organization classification. SC was used in the Clerkenwell Public Library in North London where Brown was chief librarian and was regarded as particularly suitable for public libraries in Great Britain.

The phenomenon basis for classification has not been widely accepted, and no completely phenomenon-based scheme has been tried. Special "phenomenon classes," however, have been included in two modern classification systems, the Broad System of Ordering (BSO) and BC2. In these two knowledge organization classifications, the

phenomenon class acts as a place where grouping on the basis of some phenomenon can occur if desired. That is, all the materials that can be said to focus on one phenomenon can be gathered together, even though these materials would normally be scattered throughout the classification. All materials on “logic,” for example, can be brought together in one place in the classification instead of being scattered in various disciplines such as philosophy, computer science, and mathematics. If desired, more than one phenomenon class can be established for any particular collection of documents.

The idea of basing knowledge organization classifications on phenomena is considered to be particularly useful in developing systems that can deal effectively with multidisciplinary and/or multi-format documents because the phenomenon idea corresponds to a similar trend in educational institutions, where departments are now often organized on the basis of a phenomenon (e.g., information studies, women’s studies, Canadian studies). Langridge believes, however, that “primary division by phenomena is not possible throughout a general scheme,”^[22] even though it has not been tried. One problem is that no accepted definition of “phenomenon” exists for use in knowledge organization classification. Clearly, if one intends the word to be taken in a sense broad enough to be useful, then academic disciplines, forms, and formats must also be considered to be phenomena. If only material phenomena (e.g., the Rose) are considered, however, the Langridge’s assertion seems correct. Nevertheless, the phenomenon idea may take its place in classification theory along with literary warrant and consensus as one possible basis for the content of a classification system. Phenomenon-based groupings within classification systems founded on literary warrant and/or consensus demonstrate that a single classification system can effectively use more than one principle of grouping in the same system.

The relationships among these three theories for the sources of content for a knowledge organization classification are relatively complex. Literary warrant uses the topic of documents as the basis for developing a knowledge organization classification. Consensus, likewise, considers the topics of documents, but then extends the idea of literary warrant to include the position the authors take about these topics. It posits that authors will increasingly adopt the same point of view toward the topics. Clearly, too, the idea of consensus implies that many documents will be created based on consensual ideas. It follows that more and more documents will presumably be published validating this consensus. The idea of basing at least part of a system on a phenomenon of particular interest in a particular library includes not only the content of the documents themselves, their authors, and their topics, but also extends these other two theories to include the needs of the users of libraries that may have important special collections that should be kept together.

Three Types of Structure for Knowledge Organization Classification Systems

We have concentrated on theories relating to the content of a knowledge organization classification. Like natural language, however, knowledge organization classifications have a structure by which the content is organized. The most common structure for classification systems is a hierarchical arrangement with classes and their various levels of subclasses. Another structural principle for classification systems is faceted subdivision, which was introduced into library classification by S.R. Ranganathan in the first edition of CC in 1933. More recently, the biological theory of integrative levels was investigated by the British Classification Research Group (CRG) for structuring a knowledge organization classification. The CRG’s work was not successful, but the Italian Chapter of ISKO has begun investigating the theory of integrative levels more fully.

Hierarchical structure

No one definition of hierarchy is commonly accepted, but all definitions include the notion of different levels of a thing.^[23] That is, one level in a hierarchy is subdivided to create lower levels, and different kinds of levels are given names to distinguish them from each other and to show their relationships. For example, in the hierarchical downward sequence

Mammals
Mammals—Cats
Mammals—Cats—Domestic cats

Cats is subordinate to Mammals and superordinate to Domestic cats. These hierarchical vertically linked concepts are called chains. If Cats were subdivided into Domestic cats and Wild cats, those two subordinate classes of cats are considered to be coordinate with each other.

Such horizontally related coordinate classes are called arrays.

These technical terms apply to the same concepts in different relationships to each other. In the chain

Mammals
Cats
Domestic cats
Angora cats

Domestic cats is subordinate to Cats and superordinate to Angora cats. In addition, subdivision of hierarchies can be based on equally valid but conceptually quite different principles. For example,

Mammals
Cats
Domestic cats

is subdivided by kind, that is, cats are a kind of mammal, and domestic cats are a kind of cat. Equally, however, mammals could be subdivided by preferred foods, for example,

Mammals
 Carnivores
 Cats
 or
 Mammals
 Herbivores
 Cows

Similarly, things can be subdivided by function, by materials, by time, by place, or by a multitude of other characteristics of division. A characteristic of division is the concept used to create the subdivisions of a group. Clearly, the first subdivision of the whole class will have an influential effect on subsequent choices. In our example of subdivisions of mammals, the first subdivision (whether by kind or by choice of food) governs the kinds of subdivisions that can appropriately come lower in the hierarchy. The choice of subdivision principles depends on the overall purpose of the knowledge organization classification system and on the content appropriate to each class.

The idea of hierarchical levels is apparently present in all cultures,^[24] and until the work of S.R. Ranganathan beginning in the 1920s, classification systems for knowledge organization were all hierarchically structured. That kind of structure was not questioned. For example, Melvil Dewey assumed a hierarchical structure and developed his classification system in such a way that the structure was more important than the content. He wrote

In all the work, philosophical theory and accuracy have been made to yield to practical usefulness. The impossibility of making a satisfactory classification of all knowledge... has been appreciated from the beginning, and nothing of the kind attempted. Theoretical harmony and exactness has been repeatedly sacrificed to the practical requirements of the library... Theoretically, the division of every subject into just [ten] heads is absurd.^[25]

In this passage, Dewey asserts that the structure of DDC is absurd because subdivision of every class and subclass into tens cannot be justified on any theoretical basis, but the structure is nevertheless more important than its content because it improved library practice. He advocated and adopted this kind of decimal subdivision because it was practical and he ignored issues of theoretical elegance or accuracy. Dewey's position on this issue is very strong—not even inaccurate names for content should stand in the way of the practicality of the structure of his classification system for arranging books on shelves and surrogate records for these books in catalogs.

Various criteria have been developed for the hierarchies of knowledge organization classification systems. In the principle of maximal efficiency, Bliss, for example,

provided two similar criteria, “gradation in speciality” and “subordination.” Gradation in speciality meant that basic classes, particularly in the sciences, should lead to their derivatives. For example, chemistry should lead to chemical technology. Subordination meant that special subjects should be subordinate to general subjects. For example, Platonic philosophy should be subordinate to philosophy in general. In addition, writers usually mention that subdivision in a hierarchy should be well-modulated and big leaps in subordination should be avoided. For example, mammals should not jump down suddenly from mammals in general to Angora kittens with no intervening hierarchical steps. In general, these criteria are applied to knowledge organization classifications in which the schedules of the system were printed and established in the hierarchical order required by the creator of the system. These kinds of systems are enumerative and precoordinated knowledge organization classification systems, as discussed above.

Facet structure

A facet is a group formed by the consistent application of only one characteristic of division at a time. Ideally, a facet contains all the terms that could reasonably be used when we want to subdivide by a certain characteristic. Each element in a facet is called a focus (plural foci). For example, in subdividing furniture by the materials facet, we might include wood, plastic, and metal, but not cobwebs, which cannot be a focus of the materials facet for Furniture because cobwebs are not used to make furniture. Similarly, in subdividing Furniture by kinds, we might include tables, chairs, lamps, and beds, but not automobiles because automobiles are not a kind of furniture. If we want to subdivide more deeply to another hierarchical level, we can use a subfacet of the original facet. For example, if Furniture is subdivided by kind to produce Chairs, Chairs can also be subdivided by kind to produce a list of kinds of chairs (e.g., dining room chair, kitchen chair, rocking chair, armchair, and lounge chair) or by material to produce a list of all the materials chairs are commonly made of (e.g., metal, plastic, wood). In contrast, we would not subdivide furniture into such groups as “metal chairs” or “plastic lamps” because more than one characteristic of division is operating at each level.

S.R. Ranganathan, who began his career as a mathematician, became university librarian at the University of Madras in India, and was subsequently sent to England to study library science in 1924. While he was in London, he began to develop the idea of faceted structures for knowledge organization classification. He postulated that there were five fundamental categories that could be used to state notationally the content of documents, both books, and other kinds of texts like journal entries. The five fundamental categories were assumed to be personality, matter, energy, space, and time. These five facets were established in his famous “facet formula” PMEST. The

Personality facet was the basic idea, entity, or concept of the document. The Matter facet dealt with the substances, properties, or materials involved. The Energy facet was the processes, operations, or activities involved. The Space facet included nations, geographic features, etc., as appropriate. The Time facet included periods, dates, seasons, etc., as appropriate. The issues raised by these five facets have generated considerable discussion in the literatures of the library and information sciences. It is important to note that the five fundamental categories were postulated, that is, not proven.

Ranganathan's principles of analytico-synthetic classification were supported by these five fundamental categories. In analytico-synthetic classification, unlike enumerative classification, the content of a document was to be analyzed into separate concepts that each was assumed to belong to one of the five fundamental categories. These individual concepts would then be given the appropriate notational element, and these notational elements were then synthesized into a notational statement that expressed the subject of the document. In general, the schedules of an analytico-synthetic knowledge organization classification are much shorter than the schedules of an enumerative classification because all possible combinations of notation do not have to be enumerated and listed in the schedules. On the journey back to India in 1925, Ranganathan began work on the CC, which was first published in 1933.

The theory of facet analysis was primarily a theory of structure for creating a notational statement by combining separate notational elements that, when joined together, would express the subjects of documents. The facet structure is often discussed, however, as if it were the opposite of hierarchical structure. Faceted knowledge organization classification can include hierarchical structures such as hierarchical levels of sub-facets, and the two kinds of structure are not mutually exclusive. A faceted knowledge organization classification is, however, fundamentally unlike an enumerative structure because a faceted structure does not require all possible combinations to be established in the classification schedules. Instead, a faceted classification establishes facets and their foci and then allows notational combinations from the facets and foci to be formed in order to state the subject of a document. It is also sometimes stated that faceted classification shows the relationships between the elements present in a document and stated in a notation. This assertion is invalid because the five fundamental categories do not stand in a constant relationship with each other within different documents. For example, if we have two documents about "the influence of the moon on the tides," one may emphasize the phenomenon of gravitational force (Energy facet) and the other may emphasize the tidal response (Materials facet) to gravitational force. In this case, the notation for both documents will be the same, but the content of the documents is quite different.

Ranganathan's contribution was to apply the principles of mathematical set theory to concepts as a way of making

a classificatory structure predictable, rational, and economical. Like the other knowledge organization classifications we have discussed, CC had main classes based on academic disciplines as the forms of knowledge. In CC, these were called basic classes. Each basic class had a standard facet formula for its own content that was a variation on the PMEST formula. In addition, it became clear that documents often contained more than five conceptual elements that corresponded exactly to the five fundamental facets. For this reason, Ranganathan extended the facet formula in practice in such a way that more than one occurrence of various facets could be used in what were called rounds and levels of notation.

Ranganathan's basic ideas were brought to Great Britain in 1951 in a textbook called *The Fundamentals of Library Classification* by B.I. Palmer and A.J. Wells.^[26] Before that publication, Ranganathan's ideas were known in Great Britain, but his explanations of technical terms were considered obscure. For example, Ranganathan did not use the term "facet" in the present meaning of the term until the third edition of CC in 1950. Before that, Ranganathan used the terms "standard unit," "sequence," or "train of characteristics" for what he later called a "facet." In his *Prolegomena to Library Classification*, for example, he wrote

Complete Division of a universe is the process of extending division of that universe on the basis of a sequence of characteristics until no multiple group is left.^[27]

Further, his mathematical background suggested terms such as postulates, rules, laws, and formulae to him, and he brought those terms into knowledge organization classification theory. These kinds of terms added to the difficulty others sometimes encountered in understanding his ideas and how they could be applied in knowledge organization theories and systems for the library and information sciences. Palmer and Wells' textbook clarified Ranganathan's vocabulary and concepts for English classificationists, classifiers, and students.

In consequence, Ranganathan's ideas rapidly caught on, and in 1955 the CRG in England published a manifesto called "The Need for a Faceted Classification as the Basis of All Methods of Information Retrieval."^[28] The members of the CRG had analyzed the theory, principles, and practices of existing knowledge organization classifications and found that they were inadequate for the tasks for which they had been designed. The CRG extolled the theory of facet analysis and the analytico-synthetic facet method as the only method that would be adequate for the increasing number of documents that were being published, many of them on highly detailed, multidisciplinary, and specialized topics. The members of the CRG created a number of special knowledge organization classifications using Ranganathan's principles, and a manual on how to make faceted systems was published.^[29]

Despite the group's admiration for Ranganathan's work, however, they disagreed with his postulation of only five fundamental categories. The CRG extended the idea of fundamental categories to include other categories that seemed necessary for the particular classificatory domain they were considering. For example, Vickery's classification for soil science had nine facets, and D.J. Foskett's classification for container manufacture had four facets and one set of common subdivisions (both classifications are in Vickery^[30]). These differences may have arisen from the work of CRG's members in special libraries and bibliographic venues.

Ranganathan himself disagreed with the CRG's emphasis on special knowledge organization systems for domains smaller than the whole universe of knowledge because he saw the world of knowledge as a unitary circular structure, as expressed in the acronym APUPA. The center of the world of knowledge was the Umbra, surrounded by concentric circles of Penumbra and Alien areas that were increasingly farther away from the center. The CRG, too, realized that special domains could not entirely be separated from the rest of the world of knowledge. They saw their special knowledge organization classifications as consisting of a core area of knowledge surrounded by fringe topics that were related to the core in some particular way. For example, a knowledge organization for a special area of knowledge would also need to accommodate educational, legal, and ethical issues for that area, and the CRG also recognized that these fringe areas were actually complete core fields of study in themselves.

The CRG's research during this period was highly fruitful. After their work on the North Atlantic Treaty Organization (NATO) grant was over, as discussed below, the Group produced LISA (Library and Information Science Abstracts) knowledge organization classification, their most successful scheme. In addition, Derek Austin began work on Preserved Context Indexing System (PRECIS), and Jack Mills began work on BC2. Although BC2 is not yet finished, it is generally considered to be the most theoretically sophisticated modern knowledge organization classification. It is based on the research the CRG conducted under the NATO grant and it uses the analytico-synthetic theory of facet analysis and retroactive notation, which was developed as in part as a result of the CRG's work on a general scheme. BC2 is regarded as a fully-faceted scheme in the sense that each main class uses facet theories and principles exclusively in its development. The Introduction to BC2 is probably the most comprehensive discussion of facet theory, principles, and methods outside Ranganathan's own writings,^[31] and an exposition of BC2's principles appears in Mills.^[32]

Facet analysis and faceted classification theories have been highly influential in the revision of the major general classification schemes such as DDC, UDC, and LCC. Currently, research is being conducted on revising UDC on

the basis of work carried out for BC2.^[33] Further, facet theories, principles, and methods are considered particularly effective for Web-based classification and information retrieval, and interest in elements of facet theories and principles are increasing in computer science, in other technical areas, and for relatively untrained computer users (discussion and examples can be found at Denton).^[34] Ranganathan's theoretical work on structural issues in knowledge organization is generally seen as the most fruitful and highly-regarded knowledge organization work in the twentieth century. The influence of facet theory and the CRG's work has been brought up to date in a current entry with the same title as the CRG's original paper on faceted classification and in a special issue of the journal *Axiomathes*.^[35]

Theory of integrative levels

In 1962, NATO gave the Library Association £5000 (about \$14,000) to develop a new general classification system for scientific documents. The Library Association approached the CRG for this work, and the group began to create this new system. For the new system, the CRG planned to use facet analysis as the basic structural principle and method, and they decided to use the theory of integrative levels to design how the classes would be formed. The theory of integrative levels is a biological theory about how individual cells combine into different organisms.^[36,37] This theory meshed neatly with facet theory because it appeared to be a special case of an analytico-synthetic method worked out for the biological sciences. The CRG was unable, however, to create a knowledge organization classification system based on the theory of integrative levels, and the NATO grant was not renewed when the Group reapplied in 1969.

The theory of integrative levels was based on a series of Laws of the Levels and Rules of Explanation. As described by the CRG, the theory of integrative levels maintains

that the world of things evolves from the simple towards the complex by an accumulation of properties, and that, at a succession of levels, these aggregations reach new degrees of complexity and become new wholes, with individual and unique identities. Each whole is greater than the sum of its parts, and ceases to possess its identity if broken down again. It acts as a unit, and the units at each level can engage in processes characteristic of that level; an influence acting on one part of the unit affects the whole unit, even though other parts may continue to function as before.^[38]

The description of the CRG's examination of integrative levels and the conclusions it reached are presented in their report *Classification and Information Control*.^[39] A number of problems arose, among which were their efforts to

find appropriate levels with which to analyze the ideas that human beings created and worked with (which the CRG termed “mentefacts”) and also the physical creations of human beings (e.g., works of art). Further, the group realized that a general knowledge organization classification for documents would need to classify documents about certain things, not the things themselves. This situation became known as “the Chinese plate syndrome,” which the CRG used to draw the distinction between classifying books about Chinese plates and classifying the Chinese plates themselves.^[40]

The CRG was not able to resolve the problems they faced, and they abandoned the theory of integrative levels when the NATO grant ran out was not renewed. Nevertheless, the theory of integrative levels remained intriguing and became the basis for Dahlberg’s Information Coding Classification (ICC).^[41] More recently, the Italian chapter of ISKO (<http://www.iskoi.org/>) has embarked on a series of investigations into the theory of integrative levels and has begun developing the Integrative Levels Classification (ILC).^[42] These investigations appear to be fruitful new directions in research on the structure(s) of knowledge organization classification.

Notation for a Knowledge Organization Classification System

Notation is used in many fields as a way of coding and communicating complex ideas, such as music, dance, and mathematics.^[43] All the knowledge organization classification issues we have discussed have implications for notational systems. There is general agreement that the notation is the final step in creating a knowledge organization classification. Once a notation is in place, the system is considered to be frozen. At that point, it is more difficult (but not impossible) to make a system hospitable by adding new concepts at the right places. Notational development is important for knowledge organization classification because the notation shows the position of the concept in the schedules and that concept’s relationship(s) to other concepts. Notation thus allows individual documents and related groups of documents to be retrieved. In theory, notation is a device that describes the structure and content of a knowledge organization system without using words. Ranganathan aspired to create an “artificial classificatory language”^[44] that would systematize and regularize notation.

Discussions of desiderata for notation have included a number of characteristics, for example, it should be pure (use only numbers or only letters); it should be mixed (letters, numbers and/or other symbols); it should be expressive (show the hierarchical level of the concept in the system); it should be mnemonic (suggest its own meaning in some way); it should be short (for memorability); and it should be pronounceable. Clearly, all of these characteristics cannot occur together. For example, an

expressive notation that shows a hierarchical depth of 15 levels of subdivision cannot also be short and will probably not also be memorable or pronounceable. A useful chart showing how various kinds of notations work and how they compare with each other in length appears in A. C. Foskett’s *The Subject Approach to Information*.^[45] Detail about the CRG’s research into notation appears in Vickery.^[46]

Although Dewey probably did not invent the decimal notation that DDC uses, he popularized it and demonstrated its usefulness in bringing books on like topics together on the shelves. Before DDC, books were usually arranged on shelves in broad classes with an ordinal call number that was based on the book’s accession number. That practice was called a fixed place notation and meant that books on the same topic would not be shelved in proximity to one another unless they had been acquired at the same time. One argument in favor of fixed place notations was that a library patron could learn where a favorite book was placed and find it immediately because it was always shelved in the same place. That characteristic was helpful at a time when much indoor lighting used candlelight, or, at most, oil or gas lights. The idea that decimal notation was superior to fixed place notation spread quickly at least in part because of Dewey’s charismatic personality and tireless promotion of DDC. As interest in Ranganathan’s ideas became established, faceted classification structures created a renewed interest in notation because an analytico-synthetic faceted system depended on being able to notate separate content elements to express the subject of a document. This development meant that two new issues had to be addressed concurrently when creating a notational system for a faceted classification: citation order and facet indicators.

Citation order

A citation order for the separate elements of a faceted notation needed to be established. Citation order is the sequence in which notational elements are set down in a complete notation. The analytico-synthetic method meant that the subject of the document was analyzed into its parts, each of which was given its own notation. Once these notational elements were identified for the document, they had to be synthesized in a standard predictable order. The requirements of information retrieval meant that these stand-alone notational elements could not be combined randomly. If random order were used, it would not be possible to predict what each notational element meant in the notation as a whole and accurate retrieval could not occur. For this reason, a standard notational sequence had to be established.

Ranganathan’s PMEST facet formula specified the citation order in which notational elements needed to be combined for CC. Other faceted classifications, for example, those developed by the CRG, have different citation

orders based on the requirements of knowledge organization classifications. The group did, however, develop what they called a “standard” citation order that could be established for each class. The CRG’s standard citation order was class, thing (purpose), kind, part, property, process, operation, agent, space and time. This standard citation order added detail and flexibility to Ranganathan’s PMEST facet formula. In the CRG’s version, thing (purpose) corresponded to personality; kind, part and property were included in material; and process, operation and agent were included in energy. Space and time always stand at the end of a notation and are included in every faceted classification system and in most enumerative ones. Time is usually the last element because it is considered to be a more abstract concept than space and has no universal referent.

Citation order did not pose a similarly difficult problem for non-faceted enumerative notations because the schedules of that kind of system did not allow the flexibility of combining notational elements at will. The device of combining notational elements was not entirely new with faceted systems, however. For example, the second edition of DDC (1885) allowed one to subdivide certain topics geographically by adding numbers from the 900 class to the notation for the topic. The topics that could be subdivided in this way were shown in Table 1 of the second edition. Similarly, UDC, which was based on the fifth edition of DDC, provided from the beginning seven auxiliary tables for this kind of notational synthesis, six of which are still included in the UDC schedules today. Individual schedules in LCC also have tables for combining notations. SC had an auxiliary table, the categorical table, which provided about 900 “standpoints” by which any topic in the schedules could be modified. In addition, SC allowed both intra- and inter-facet notational synthesis, that is, synthesis within one facet and between different facets. The rationale for this kind of notational synthesis in enumerative systems is that the use of auxiliary tables meant that every possible combination does not have to be printed in the schedules. Further, there is usually some choice about when to use the auxiliary tables (except in LCC). Thus, in enumerative knowledge organization systems notational synthesis is seen as device to provide economy in the schedules and a citation order is built into the schedules, but in faceted systems notational synthesis is a fundamental principle that is driven by the theory of analytico-synthetic classification. In this case, citation order must be explicitly decided and rationalized by the classificationist.

Facet indicators

As we have seen, at the advent of Ranganathan’s analytico-synthetic method in classification, the level of analysis of an information object changed from notation summarizing the whole information object to notation expressing different elements that would, when combined, describe the

intellectual characteristics of the document. Thus, in addition to requiring a citation order, analytico-synthetic theory, principles, and practices required facet indicators. Facet indicators are punctuation marks or other symbols that show where the synthesized notation is divided into its separate facets. Facet indicators are required so that separate notational elements may be used in information retrieval. Without an indication of where a new facet begins: 1) one cannot search for an instance of a notational element and 2) one cannot add digits to the notation for that facet when required by the demands of hospitality. In the first edition of CC, Ranganathan used the colon as a facet indicator between the notation for each of the facets. Later, different punctuation marks were inserted at the beginning of each facet. For example, the topic “Classification of theses by the LCC classification system in Canadian university libraries in 1978” would be notated 234;494:51;M98.72’N78 where 2 was the basic class for library science; 34 was the personality facet for university libraries ; 494 was the matter facet for theses ; :51M98 was the energy facet for classification by LCC ;.72 was the space facet for Canada; and ‘N78 was the time facet for 1978.

Like citation order, facet indicators had been used before Ranganathan’s views were known, but in a somewhat different way and without a theoretical basis. UDC used what were essentially facet indicators from the beginning, although they were called “signs of association.” UDC has, however, no prescribed citation order, and it is thus possible to arrange notational elements in the way that is most useful for a particular situation. It should be remembered, too, that the UDC was not created as a knowledge organization classification for books on shelves, so that the problems created by differing citation orders are not as prominent as they are for a knowledge organization system for shelving. For example, notation for the topic “A thesis in French on the classification of books on education in Canada in 1979, written from the economics point of view” would be notated 025.4:37.003.1(71)“1979”(043) = 40 but could be written in a different order if required. 025.4 stands for BC; :37 means in relation to education; .003.1 means from the economic point of view; “1979” means the date; (043) means thesis; and = 40 means in French. UDC has undergone many revisions since its beginning, and the meanings of these signs of association have changed periodically. Nevertheless, the influence of UDC on other classificationists and classification systems has been strong. The most comprehensive work on the origins and development of UDC is Rayward.^[47] A shorter treatment appears in McIlwaine.^[48]

As we can see from these examples, facet indicators create lengthy and complex notations. Although they were necessary to implement the theory of faceted classification, these indicators produced notations that were considered too complex to be easily understood and too long to

be given to documents, especially for the spines of books. These issues were particularly important in an era when library classifications were used primarily to organize books on shelves (except for UDC).

The CRG undertook a number of experiments on notation, and probably the most successful was retroactive notation. Retroactive notation has been used in a number of schemes, principally in BC2. Retroactive notation does not need facet indicators, and it can be either numerical (0–9) or alphabetical. It mechanizes notational synthesis because the citation order is built into the classification schedules. In a retroactive notation, the order of the schedules is from general to specific (moving from the beginning of the schedules to the end), but the notation is applied from the specific to the general (moving from the end of the schedules to the beginning). When devising a retroactive notation, only letters in the alphabet that come after the initial letter of the notation are used. For example, the topic “a program of training for the advertising of public utilities” might have the notation ttvstwrw or ttv stw rw. We can see that the first notational element (ttv), which comes at the end of the schedules, is followed by the notational element (stw). In this example, s is closer to the beginning of the alphabet than its immediately preceding letter (v). Therefore, s begins a new facet. Similarly, in the next notational element (rw), r is closer to the beginning of the alphabet than its immediately preceding letter (w). Therefore, r begins a new facet. Retroactive notation can thus be checked by referring to alphabetical order and this kind of checking is a quick and easy procedure for computers to do. It creates a shorter notation because no facet indicators are needed, but devising the schedules is difficult. This example was developed from Barbara Kyle’s classification for the social sciences in Kyle.^[49] Retroactive notation has, however, been suggested as appropriate for computer applications because of the power of computers to analyze long strings text and a suggested system that uses some of the characteristics of retroactive notation has been developed.^[50]

CONCLUSION: THE THEORIES BROUGHT TOGETHER

Ranganathan believed that knowledge organization classification had three planes: the idea plane (the overall conception of the system); the verbal plane (the schedules and index of the system); and the notational plane (the way the concepts in the schedules were expressed in notation). The separation of topics in this entry into content, structure, and notation is roughly analogous to Ranganathan’s three planes of work. As we have seen, from their beginnings in the late nineteenth century to the present, knowledge organization classification systems have undergone major shifts in all three planes. The

initial enumerative classifications (e.g., DDC, LCC, UDC, SC) can be thought of as “universe of knowledge” classifications. That is, they began with the whole universe of knowledge and subdivided it from the top down in successive steps to create classes and subclasses at various levels of hierarchical depth. Once the schedules were arranged in the desired order, a notation was applied. As theoretical development proceeded through Ranganathan and the CRG, this top-down universe of knowledge classification systems was partially transformed into bottom-up “universe of concepts” classification systems. Wilson distinguished between universe of knowledge classifications and universe of concepts classifications in Wilson.^[51] That is, within each class and subclass, the most important concepts were identified first and their facets and subfacets were then established. On the basis of Ranganathan’s theory of analytico-synthetic classification theories, principles and methods, concepts were identified in documents, and notation was assigned to each concept. These notational elements were then synthesized in the correct citation order that had been established for the knowledge organization classification. The development of BC2 is described in Mills.^[52]

BC2 is the best example of this kind of classificatory thought, but all the major classification theories and systems have been revised to a greater or lesser extent on the basis of facet theory and its extensions. Library and information knowledge organization classification theories and systems have influenced and re-influenced each other throughout their evolutionary histories. In a rough chronological sequence, DDC was the basis for UDC, which was influential in the development of CC. Facet theory and method moved through all the systems and came to their highest point of development in BC2. Facet theory and method have then retroactively influenced DDC, UDC, and CC. CC has influenced all the others in both theoretical and practical ways, and they have all influenced the various revisions of CC. This analysis is based on Cockshutt.^[53] Thus, despite the differences in concept, application, and history of the various knowledge organization classifications, they share with each other important theoretical developments that have occurred throughout their lives. In addition, it must be remembered that all the theories and systems that have been discussed are constrained by the cultural warrants of their times and places because “classification systems are intellectual, and fundamentally also political, constructs: they represent, and impose, a view of the world at a certain time and in a certain environment.”^[54]

Clinical Decision-Support Systems

Kai Zheng

Department of Health Management and Policy, University of Michigan, Ann Arbor, Michigan, U.S.A.

Abstract

Clinical decision-support systems (CDSS) apply best-known medical knowledge to patient data for the purpose of generating case-specific decision-support advice. CDSS forms the cornerstone of health informatics research and practice. It is an embedded concept in almost all major clinical information systems and plays an instrumental role in helping health care achieve its ultimate goal: providing high-quality patient care while, at the same time, assuring patient safety and reducing costs. This entry introduces the concept of clinical decision support from early generation artificial intelligence-based systems to the evolution of modern systems based on evidence-based clinical guidelines. The discussion also includes the key technological considerations of CDSS and the barriers inhibiting its widespread adoption and effective use.

INTRODUCTION

The notion that artificial intelligence (AI) might one day rival the decision-making capability of human brain sparked the first generation of computerized clinical decision-support systems (CDSS) developed from the 1960s into the 1980s.^[1,2] However, years of trials and frustrations convinced AI enthusiasts that the enormous variations in patient care cannot be reduced to systematic decision making to render qualitative medical treatments.^[3] These limitations became even more apparent with the increasing awareness that patient care outcomes are also subject to other factors including quality- and value-of-life judgments, economic and psychosocial considerations, and social well-being of the patient as a whole. This brought a disappointing close to the first chapter in the use of computers to aid in medical decision-making.^[4]

The story did not end there. Computerized clinical information systems proliferate throughout health care organizations today, significantly reducing the costs to acquire and store patient data. These changes, however, have invited new challenges, including an explosion of patient information that far exceeds any practitioner's capability of processing such data.^[5] This situation is further compounded by a wellspring of medical knowledge resulting from the "evidence-based medicine" (EBM) movement over the past 20 years that has revolutionized the way medicine is practiced. EBM requires physicians to rely less on their own experience and more on the current best evidence in making decisions about the care of individual patients.^[6] Unfortunately, "current best evidence" is a temporal concept that may become outdated rapidly as medical research advances or the mechanisms causing diseases change (e.g., new varieties of flu virus).

Further, the U.S. health care system has been criticized for its high costs, low efficiency, poor quality, and unacceptable rates of preventable medical errors. In 2007, \$2.2 trillion or 16.3% of national gross domestic product (GDP) was spent on health care in the United States,^[7] while this number was only 8.7% on average in other industrialized countries, based on 2006 data.^[8] Despite the twofold higher health care expenditure, the quality of care provided in the United States ranks last among major industrialized countries.^[9] As a result, 31% of Americans rated the U.S. health care system as "poor" in 2008.^[10] Further, the landmark 2001 report published by the Institute of Medicine, *To Err is Human: Building a Safer Health System*, showed that preventable medical errors in the U.S. health care system cost a total of 44,000–98,000 patient lives and \$17–29 billion a year.^[11] In response to these challenges, regulatory bodies and payer systems are actively establishing new regulations and incentive policies to assure health care institutions operate optimally. Joint Commission on the Accreditation of Healthcare Organizations (JCAHO, <http://www.jointcommission.org/>), for example, publishes *Comprehensive Accreditation Manual for Hospitals* every year articulating a wide range of accreditation criteria on facility operation, care provision, and patient safety. Similarly, the National Committee for Quality Assurance (<http://www.ncqa.org>) specifies a comprehensive set of measures for monitoring patient care performance through its annual publication *The Healthcare Effectiveness Data and Information Set (HEDIS)*. While these may help to address the problems in U.S. health care, they also add a new layer of complexity to the already chaotic clinical workspace. This is the reason the medical community is embracing more than ever the idea of using computer systems to aid in medical decision making.

CLINICAL DECISION-SUPPORT SYSTEMS

Broadly speaking, a decision-support system is an interactive, flexible, and adaptable computer-based information system developed specifically for supporting the solution of a nonstructured management problem for improved decision making. It utilizes data, provides an easy-to-use interface, and allows for the decision maker's own insights.^[12] Google Maps™ (<http://maps.google.com>) provides a good example. The site applies intelligent algorithms to geographic data to provide “optimal” routes for traveling from location A to location B while, at the same time, allowing the travel planner to manually intervene in the process, such as creating a more preferred route with click-and-drag options.

Likewise, in the health care arena, clinical decision-support systems provide clinicians, staff, patients, and other individuals with knowledge and specific, individualized information, intelligently filtered and presented at appropriate times, to enhance clinical performance and patient outcomes. It encompasses a variety of tools and interventions such as computerized alerts and reminders, clinical guidelines, order sets, patient data reports and dashboards, documentation templates, and diagnostic support.^[13] The essential component of CDSS is *inference engine*, which applies the knowledge stored in a knowledge base to patient data to derive case-specific recommendations. CDSS is usually interfaced with, or as a part of, other clinical information systems such as electronic health records (EHR) or computerized provider order entry (CPOE) systems. For example, every full-fledged commercial EHR system provides certain types of electronic templates for managing chronic disease conditions. These templates offer individualized treatment and lifestyle change advice based on clinical guidelines and patient data.

With its capability of generating decision-support alerts warning against drug–drug interactions and drug–allergy interactions, CDSS is being increasingly mandated by regulatory bodies and advocacy groups such as JACHO, the Leapfrog Group for Patient Safety (Leapfrog, <http://www.leapfroggroup.org/>), and the Certification Commission for Healthcare Information Technology (CCHIT, <http://www.cchit.org/>). The JACHO accreditation manual has a dedicated Management of Information section clearly specifying the data requirements for enabling clinical decision support. Leapfrog, a voluntary group of large employers that ranks hospitals based on their quality and safety performance, has specific requirements to evaluate whether a hospital is equipped with CPOE decision-support systems capable of warning against drug interaction, allergy, and overdose. CCHIT, a recognized certification body (RCB), incorporates the clinical decision-support provision as a key component of its clinical information system certification process.

History of Clinical Decision Support

Started in the 1960s, the initial objective of introducing computers into medical practice was very clear: to provide doctors with decision aids using AI-based medical diagnostic reasoning. The enthusiasm was primarily spurred by the capability of computers to solve complex decision models in real time. This stream of research eventually developed into a dedicated discipline, Artificial Intelligence in Medicine (AIM), with wide appeal and broad consensus for optimism. In 1970, Schwartz announced in the *New England Journal of Medicine* that clinical computing would likely be commonplace in the “not too distant future.”^[14] *DXplain*, shown in Fig. 1, is a representative example of the early generation diagnostic tool. Developed at the Massachusetts General Hospital, *DXplain* uses a modified form of Bayesian logic to produce a ranked list of possible diagnoses based on symptom manifestations. Table 1 lists several other influential systems developed during this time period. For a comprehensive bibliography of these early generation CDSS systems, readers can refer to Miller 1994.^[15]

Unfortunately, the plethora of clinical computing, as predicted by many, never occurred. A large number of AI-based diagnostic reasoning systems were developed and tested, but most was not adopted in practice. A plausible reason accounting for this failure is that the AI-based diagnostic reasoning “functioned more like the ‘Greek Oracle’ rather than permitting a more flexible, interactive approach” (p. 4).^[2] A “decision-making,” rather than a “decision-supporting” structure, was perceived by physicians as a threat to clinician autonomy.^[2] Moreover, most of these early generation systems were stand-alone, self-contained applications. They were not integrated with other computerized systems supporting hospital operation and patient data management, which were not readily available at the time. As a result, the decision-support advice generated by these early generation CDSS was often inaccurate or irrelevant. For example, Berner et al. (1994) tested four diagnostic systems and found that the proportion of correct diagnoses ranged from 0.52 to 0.71, and the mean proportion of relevant diagnoses ranged from 0.19 to 0.37.^[16] This level of performance made the adoption of such systems for treating real patients unrealistic. Another major reason accounting for the failure of early generation CDSS was the lack of financial returns. The dominant pay-for-service model—reimbursement was determined based on what was done rather than how well it was done—provided little incentives for medical practices to invest in expensive computer-based decision-support technology.

New Generation of Guideline-Based CDSS

The use of computerized clinical information systems to support hospital operation as well as clinical activities

Table 1 Examples of early generation clinical decision-support systems.

De Dombal	1972	Developed at the Leeds University, United Kingdom, De Dombal is a clinical decision-support tool that uses naive Bayesian approach to provide automated reasoning under uncertainty for diagnosing acute abdominal pain and recommending the need for surgery.
INTERNIST I	1974	INTERNIST I is a rule-based expert system for solving complex diagnostic problems in general internal medicine. It was developed at the University of Pittsburgh and later commercialized under the brand name Quick Medical Reference (QMR).
MYCIN	1976	MYCIN is a rule-based expert system developed at Stanford University. It was used to diagnose and recommend treatments for certain blood infections and other infectious diseases.
DXplain	1984	Developed at Massachusetts General Hospital, DXplain uses a modified form of Bayesian logic to produce a ranked list of diagnoses that might explain or be associated with the clinical manifestations.

started to flourish in the early 1990s. Besides the significant technological breakthroughs, including the availability of enterprise-level database management systems (DBMS) and health data standards such as ICD and HL7, new legislation and advocacy by federal funding agencies also played a key role. International Statistical Classification of Diseases: Standard diagnostic classification developed by the World Health Organization (WHO) for its member states to report mortality and morbidity statistics. In the United States, ICD-9-CM (ICD 9th Revision, Clinical Modification) is widely used to codify diagnostic data for administrative (such as billing) purposes. <http://www.cdc.gov/nchs/dataawh/ftp/ftpICD9/ftpICD9.htm>. Health Level Seven (HL7) is an all-volunteer, not-for-profit organization. It oversees the development of international health data exchange standards. <http://www.hl7.org>. Financial investments to implement large-scale health IT systems were made by the Agency for Healthcare Research and Quality (AHRQ, <http://healthit.ahrq.gov>), Health Resources and Services Administration (HRSA, <http://www.hrsa.gov/healthit/>), and many other foundations and private funding sources. Insurance companies have also been actively engaged. They either

funded health IT directly, or provided financial incentives to medical practices for adopting information technology. The purpose was to reduce administrative costs in processing paper-based claims, thereby improving the quality and timeliness of health data submitted by medical facilities.

This provides a platform warranting the rise of a new generation of CDSS. Fewer of these new generation systems remain as stand-alones because of the need to provide clinicians with a unified interface to access all patient data and all clinical functionalities. Instead, CDSS often appears as modules embedded in other computerized systems, such as EHR and CPOE. Compared with their AI-based ancestors, these new generation systems represent a new class of CDSS—evidence-adaptive decision support—that provides decision aids with a knowledge base constructed from, and continually adapting to, new evidence based on research and practice, i.e., EBM. EBM is the conscientious, explicit, and judicious use of current best evidence in making decisions about the care of individual patients (6). It distills scientific evidence from the systematic analysis of medical literature using statistical or data mining approaches.^[17] These systems are primarily used to help improve the coherence of preventive care and chronic disease management guidelines. A significant portion of clinical decision support is also provided using rather primitive database look-up rules. For example, dosage levels may be suggested based on patient age and body mass index (BMI), or prompts may appear for medication interactions based on commercially available medication lexicons, or reminders for vaccines based on well-specified childhood or adulthood vaccination schedules. The rationale behind these CDSS systems is simple: the majority of quality care problems and patient safety issues are due to human omissions, rather than lack of medical knowledge. Hence, CDSS should focus on “reminding” clinicians to avoid potential omissions instead of providing direct diagnostic aids by assuming clinicians are unable to solve a problem. As shown by Garg et al. 2005, such passive reminding systems are far more effective than proactive diagnostic systems.^[18]

In 2006, the American Medical Informatics Association (AMIA) published *Roadmap for National Action on Clinical Decision Support*, which identifies three key objectives for CDSS research and practice: 1) Best Knowledge Available When Needed; 2) High Adoption and Effective Use; and 3) Continuous Improvement of Knowledge and CDS Methods.^[19] Objective 1 of the AMIA CDS Roadmap suggests that providing clinical decision support should be based on up-to-date medical knowledge and should occur “as part of clinician workflow” and “at the time and location of decision-making” (p. 765).^[20] Objectives 2 and 3 are related to medical knowledge engineering and the implementation and user resistance barriers of CDSS, which is discussed in detail in the following two sections.

Guideline Ontologies for Effective Medical Knowledge Engineering

The up-to-date medical knowledge implemented in CDSS is primarily derived from evidence-based clinical guidelines. AHRQ’s National Guideline Clearinghouse (<http://www.guideline.gov>) is the principal resource for the latest guidelines spanning a wide variety of disease areas. However, these clinical guidelines are usually disseminated as unstructured, narrative documents that often lack sufficient detail for computing. For example, a very simple guideline for breast cancer screening recommends “screening mammography, with or without clinical breast examination, every 1–2 years for women aged 40 and older.” U.S. Preventive Services Task Force, Screening for breast cancer, Recommendations and rationale. <http://www.ahrq.gov/clinic/3rduspstf/breastCancer/brcanrr.htm>. To convert this guideline into a computable form, “screening mammography,” “women,” and “age” all need to be rigorously defined with standard medical terminology, shown in Fig. 2. The location of the corresponding patient data elements and how to retrieve them must also be specified. Oftentimes, this task is not trivial. For example, “mammography” may be stored in a laboratory information system (LIS) that does not communicate with the CDSS, or the terminology representing “mammography” in the LIS may not conform to the terminology used in the CDSS.

Arden Syntax, a procedural language for representing medical logics, was introduced in 1989 to enable effective and standard-based computation of medical knowledge. It soon became a standard of the American Society for Testing and Materials (ASTM) and was later adopted by HL7. Arden Syntax provides a specification for encoding medical logic as individual rule-based procedures, also known as Medical Logic Modules (MLMs). Each MLM contains sufficient computational detail and data requirements to make a single medical decision. For example, the following MLM code determines when to issue the alert, “Consider impaired kidney function” based on the most recent creatinine level and blood urea nitrogen (BUN) test results:

```
data:
  last_creat := read last { "Creatinine
level" };
  last_BUN := read last { "BUN level" };
;;
logic:
  if last_creat < 1.5 or last_BUN > 30
  then alert_text := "Consider impaired
kidney function.";
  conclude true;
  end if;
;;
```

Arden Syntax, however, is not suitable for representing comprehensive guidelines. Each MLM represents a discrete

Fig. 2 A computerized clinical guideline flowchart.

decision-making logic, like the example above, and could easily become unmanageable as guidelines become more complex. This limitation has led to the development of several ontology-based guideline representation models.

A guideline representation ontology is a specification of elements that constitute evidence-based guidelines. It represents the elements by specifying their attributes and defining the relationships that hold them together. For example, a guideline may represent a set of medical decisions and actions (attributes) and a set of rules (relationships) that link the evaluation of a decision criterion to a set of further steps to be taken. A rigorously defined computational ontology provides considerable promise of producing computable representations that can be visualized, edited, executed, and shared using CDSS. Several ontology-based guideline representation models have been developed over the past 20 years. The influential ones include Asbru (<http://www.asgaard.tuwien.ac.at>), EON (<http://www.smi.stanford.edu/projects/eon/>), GLIF (Guideline Interchange Format, <http://www.glif.org>), and SAGE (Sharable Active Guideline Environment, <http://sage.wherever.org>), developed in the United States; and GUIDE (http://www.labmedinfo.org/research/dsg/decision_support.htm), PRODIGY (<http://www.prodigy.nhs.uk>) and PROforma (<http://www.acl.icnet.uk/lab/proforma.html>), developed in Europe. Some models, such as GLIF and SAGE, aim to achieve a general, interchangeable

format.^[21] Others, such as PRODIGY, focus on representing guidelines in specific disease areas.^[22]

Barriers to Implementing and Using Clinical Decision Support

Clinician time is the most precious resource in a medical practice. Average time for seeing each outpatient visit is less than 20 min.^[23,24] Considering other administrative time loss, the amount of time for accomplishing the actual work—examining patients, reviewing historical data, making judgments, and documenting new findings and performing treatments—is extremely limited. Any innovations that slow things down are bound to fail.

Unfortunately, very few CDSS systems benefit time efficiency. In fact, most require extra clinician time to enter patient data and review and act upon decision-support prompts. Managing complex chronic disease conditions such as diabetes, for example, is very time-consuming and often distracts clinicians from the main focus of a patient visit.^[25] As a result, the actual efficacy and effectiveness achieved by new generation CDSS are still mixed.^[17,26,27] Overriding or ignoring computer-generated decision-support advice is common,^[28] and many CDSS systems are abandoned altogether.^[29]

Patient data codification

A fundamental barrier in CDSS adoption is the need for patient data codification. All patient data must be properly codified, according to certain standard taxonomies, in order to be computed in the inference engine of a CDSS. However, picking a right code is a mechanical, time-consuming process that generally keeps clinicians away from focusing on the content of clinical documentation. The codified patient data also risks losing the narrative, story-telling nature that used to be conveyed in free-text patient notes. Moreover, numerous competing and conflicting taxonomies exist for historical reasons. ICD-9-CM, for example, is widely used in the United States to prepare diagnosis-based billing claims. Nevertheless, many clinical observations and findings are intermediate disease stages that are not necessarily “diagnoses,” and hence cannot be meaningfully represented using ICD-9-CM.^[30,31] To address this issue, new observation-oriented clinical data taxonomies, such as SNOMED-CT, have been proposed. Systematized Nomenclature of Medicine-Clinical Terms (SNOMED-CT): A clinical terminology that provides unique meanings and formal logic-based definitions for diseases, clinical findings, and procedures. <http://www.ihtsdo.org/snomed-ct/>. The National Library of Medicine also maintains the Unified Medical Language System (UMLS, <http://www.nlm.nih.gov/research/umls/>), a meta-thesaurus for translating terminologies across different medical vocabularies whenever compatible.

System interoperability

Another significant barrier inhibiting CDSS adoption is the system interoperability issue. In order to generate case-specific advice, CDSS must have access to complete and up-to-date patient data. While computerized clinical systems are now commonly used to manage a variety of patient information, many of these systems do not readily talk to each other. Creating one-to-one data exchange interfaces is possible, but can be very costly and difficult to maintain as systems constantly upgrade. Enabling patient data sharing across health care settings is further challenged by the lack of regional health data exchange networks. Personal Health Records (PHR), that allows all care providers to upload patient data to a common repository, have shown some promise as a solution to the issue. Google Health™ (<http://www.google.com/health/>) and Microsoft HealthVault™ (<http://www.healthvault.com>) are examples of PHRs that are currently being tested in the field.

Other contextual factors

Lastly, there are many other concerns in using CDSS beyond technological considerations. CDSS introduces a radical impact on patient care delivery and, in particular,

can be detrimental to the quality of point-of-care physician communication if not used properly. Using computers in front of patients and the resulting loss of eye contact is considered rude and often listed among common reasons causing user resistance.^[32] The threat to clinical autonomy is also an enduring issue for physicians. Many new-generation CDSS systems are now associated with certain evaluative mechanisms to “score” clinician performance. This unpleasant characteristic could further erode user acceptance. As Anderson et al. 1994 commented, “despite the fact that they are technologically sound, more than half of medical information systems fail because of user and staff resistance” (p. 1).^[33] These contextual human factors must be taken into account when implementing CDSS in real practice.

Case Study: The Clinical Reminder System

The clinical reminder system (CRS) was jointly developed by the H. John Heinz III School of Public Policy and Management at Carnegie Mellon University and the Western Pennsylvania Hospital (WPH). Since February 2002, CRS has been deployed in two WPH medical practices treating real patients.

CRS uses evidence-based clinical guidelines to support the management of four chronic health conditions (asthma, diabetes, hypertension, and hyperlipidemia), and five preventive care procedures (breast cancer, cervical cancer, influenza, pneumonia, and steroid-induced osteoporosis). A guideline representation model built upon existing ontologies (e.g., GLIF) was implemented in CRS for enabling structured acquisition and automated execution of evidence-based guidelines. Fig. 2 shows a sample visual representation encoded in this model. These visual representations, with embedded medical decision-making logic (shown at the bottom right corner in Fig. 2), are stored in XML files that theoretically can be shared with other CDSS systems if they implement the same underlying guideline representation model.

In order to generate case-specific reminders, CRS stores and manages comprehensive patient information, such as patient descriptors, symptoms, and orders. Standard medical vocabularies are used whenever possible. For example, ICD-9-CM is used in CRS for encoding diagnoses, CPT4 for procedural treatments, and the National Drug Code (NDC) for medication prescriptions. Current Procedural Terminology: A directory of descriptive terms and identifying codes for reporting medical services and procedures under public and private health insurance programs. CPT4, its 4th edition, is the most widely adopted version in the United States. <http://www.ama-assn.org/ama/pub/category/3113.html>. National Drug Code Directory: A directory that lists universal product identifier for human drugs. Its current edition is limited to prescription drugs and insulin products. <http://www.fda.gov/cder/ndc/>. CRS also retrieves patient data from many

Fig. 3 The main workspace of the clinical reminder system.

other hospital information systems, most in real time. The clinic staff use CRS to manage appointments, patient check-in and check-out, and record vital signs. The residents and attending physicians use CRS to document clinical observations, prescribe medication and laboratory test orders, and generate reminders to aid in their decision making. The reminders usually take the form of recommended actions to have certain tests performed, to receive vaccinations, or to discuss the pros and cons of alternative treatments. The main workspace of CRS is shown in Fig. 3, where residents and attending physicians can act upon the reminders by selecting “Performed,” “Deferred,” “Not Compliant,” among several other possible responses.

A series of research studies were conducted to examine the user adoption and acceptance of CRS. Periodical user satisfaction surveys showed that while CRS was rated “satisfactory” on all interface-related items, it received very poor user evaluation on system-related items as indicated by the survey comment, “the system is ineffective in helping me complete my work quickly.” Follow-up semi-structure interviews were conducted to investigate the issue. The results revealed several challenges to overcome, including iterative advisories (“the same reminder was generated time and time again”), cumbersome data entry (“it is too difficult and takes too

long to enter data”), workflow disruption (“slowed down my work”), solicitation for one single system (“we should have only one system to access all information needed”), disrupted physician–patient communication (“my patient felt upset when I used my computer”), and lack of guidance in the application workflow (“I don’t know where to start”). These problems are primarily associated with the sociotechnical integration issues when clinicians try to incorporate CRS into their routine clinical practice.^[34]

CONCLUSION

This entry introduces the concept, history, and key considerations and barriers to providing computerized decision support to clinicians, with a particular focus on systems that provide prompts based on evidence-based clinical guidelines. This stream of CDSS has become increasingly popular and viewed as a key solution to addressing the quality and safety problems of the U.S. health care system. Cutting-edge research is also being conducted to explore the efficacy and applicability of more sophisticated decision models particularly those accommodating decision making under uncertainty. Readers who wish to develop a full spectrum of knowledge of CDSS may refer to the OpenClinical

Project (<http://www.openclinical.org/dss.html>) or Berner's textbook *Clinical Decision Support Systems: Theory and Practice*.^[35] Practitioners interested in the design, development, and implementation of CDSS may refer to the CDSS Implementer's Guide developed by the Healthcare Information and Management Systems Society.^[36]

College Libraries

Thomas G. Kirk, Jr.

Earlham College Libraries, Earlham College, Richmond, Indiana, U.S.A.

Abstract

College libraries, through a combination of forces have made unprecedented strides in the development of access to information resources and in offering services to help students and faculty make greater use of these resources. In so doing, college libraries have become more critical to the success of the host institution. They are now poised to build on the advancements of the past 30 years to respond to the environmental changes and user expectations and to meet the challenges of being even more integral to the academic program.

INTRODUCTION

For this entry, “college libraries” includes the libraries in the 527 institutions classified as either Baccalaureate Colleges-Liberal Arts or Baccalaureate Colleges-General in the 2000 Carnegie Classification.^[1] A sampling of the 527 institutions using data from the 2000 edition of *Peterson's Guide*^[2] indicates that the average enrollment of this group is 1239 students. The libraries of these institutions average about 182,000 volumes. The averages are deceiving because the collection sizes range from 50,000 volumes to well over a million, and enrollment ranges between 98 to more than 4000 students. Therefore, neither size of collections, and thus probably neither facilities nor staff size, nor size of student body can neatly define the group. The definition of the category as having primarily or exclusively 4-year undergraduate programs is the one characteristic that the institutions share.

BACKGROUND

The history of college libraries is documented through the early 1960s in Richard Harwell's article in the earlier edition of this encyclopedia.^[3] Harwell focused largely on the development of college library buildings and collections with particular attention to special collections. However, stimulated by such publications as Daniel Gore's “zero growth,”^[4] Evan Farber's “university-library syndrome,”^[5-7] A.P. Marshall's “librarians as educators,”^[8] and William Moffett's “life and redemption this side of ARL,”^[9] in the 1970s and early 1980s, college librarians began to broaden their activities. Although the specifics of each article are important, and in fact could be the subject on a separate essay, what is especially important here is that, together, they signal the recognition of college libraries' potential to play an important role in the education of undergraduates. Since their writing, the

messages of these entries have been given substance and texture in the development of library programs.

It is important to understand the changing nature of higher education over these 30 years. As Edward Holley has indicated, the early 1970s were a time of great pessimism in higher education. Support for higher education had declined in the federal and state governments since the 1950s and 1960s, and high inflation in the economy and a sharply declining birth rate all made the future of higher education look bleak.^[10] In contrast, by the end of the millennium, inflation had declined, enrollment had increased, and a broadened social role had very much changed the ethos of higher education.^[11] As a result, the challenges faced by undergraduate libraries changed over the 30-year period. Libraries that had to make do with fewer resources in the 1960s, by the 1990s had increasing resources but faced increasing user expectations for access to information resources.

To reflect the shifting challenges in college libraries, the rest of this entry addresses six areas: the use of information technology; collection development; interlibrary loan; bibliographic instruction/information literacy; changes in assessment and accreditation standards; and library management, structure, and staffing. There are a number of other topics that might have been treated, but it is the author's judgment that these six are not only the most critical and most central to the recent developments in college libraries, but will likely be the central and critical issues in the near future.

DEVELOPMENT OF INFORMATION TECHNOLOGY

Despite the beginnings of the application of data processing in business and in large academic libraries, none of the four articles by Farber, Gore, Marshall, and Moffett mentions the potential of computer technology in

college libraries, nor is there much written on computers in college libraries in the early to mid-1960s. Although some visionaries may have seen the coming importance of computer technology in college libraries, in practice computers were of little concern for college librarians. For example, the 1974 edition of the venerable *The Administration of the College Library* by Guy Lyle, almost a textbook for college librarians, although it does discuss the potential use of computers in acquisitions, cataloging, and circulation in college libraries, it is very tentative about its role.^[12] Typical of Lyle's attitude is the conclusion to the section on circulation, where he writes:

It must be said, of course, that few college libraries, and then only the very large ones have fully automated their circulation services. . . . At what stage it is practical to make the conversion from manual or semi-automated circulation systems to a fully automated system. . . . has not yet been clearly settled.^[12]

If Farber and others had written their articles in the 1990s, they would have been compelled to discuss computer technology's impact on their topics. In fact, Farber later did so in an article discussed below.^[13] The absence of discussion of computers in college libraries in the 1960s is not a reflection on college librarian's lack of foresight but rather indicates the rapidity of change in the status of computer technology over the next 30 years. Some would say technology has been *the* critical issue and will continue to be in the future.

College libraries have generally not been leaders in the implementation of new technologies because of the equipment and labor costs of implementation and the rapid obsolescence of experimental technologies. On the other hand, college libraries have rapidly embraced technologies when standardized and relatively easy-to-implement services and products became available. Perhaps the best example is the implementation of OCLC, originally the Ohio College Library Center, and now the Online Computer Library Center. It began operations in Ohio in 1971 and spread nationally beginning a year later.^[14,15] The impetus for OCLC's development came from the large academic libraries in Ohio that funded its early development.^[16] Once the service was well established and began to spread beyond Ohio, college libraries were quick to embrace it. In recognition of the difficulty colleges had in paying for the implementation of OCLC, the W.K. Kellogg Foundation provided 302 college libraries grants to support the purchase of equipment, training, and a portion of the operational costs for a few years. OCLC is central to library operations, and almost all college libraries are members of OCLC, usually through a regional or state network.

The implementation of OCLC in college libraries had a profound and almost immediate impact on technical operations of the library (e.g., cataloging, acquisitions,

and interlibrary loan). OCLC's services replaced many manual processes within libraries' technical operations. As a result, there were changes in work assignments and the organization of technical operations within college libraries.^[17,18] However, the implementation of OCLC in college libraries was almost totally invisible to library users and had very limited impact on other parts of the library (e.g., circulation, reference).

A similar pattern of development occurred in the next major stages of technology's use in college libraries: electronic databases and library automation systems. University libraries typically began their library automation efforts by building their own systems, whereas most college libraries waited until commercial systems that could be installed and operated with modest technical support became available. Although many colleges did use CD-ROM databases and a few even networked the databases, it was not until services such as Silver Platter and First Search became available over the Internet that use of electronic databases became common and have now almost entirely replaced the use of print indexes.

Unlike the implementation of OCLC, which largely affected only technical operations of the library, online library systems or, later, the provision of online databases had a profound impact throughout the college library.^[19] The combination of integrated systems and the provision of patron access to the technology both united the organization and fundamentally expanded the role of the library. The use of the integrated system by all departments created an entity in which the entire staff had a vested interest. Because the system is the working tool for all activities, the quality of the system and information it provides is of paramount interest to all members of the library staff. Furthermore, the library staff must now work more closely with a variety of external groups to make the system work effectively. Most obvious are the technical staff who operate the system such as computer center staff, vendor, and/or consortia support staff. The other major external group is library users. The uniqueness of local system configurations, the rapidity of change and the inherent difficulties in understanding how the systems operate have increased the instructional and reference support role of librarians.

Computer technology, including OCLC, local systems, on-line bibliographic databases, and online full texts, has had a significant impact on college library budgets. First and foremost has been building and maintaining the computer infrastructure. Although some of the costs may have been absorbed by the computing services budget, these new expenses have doubtless had an impact on the library's budget through competition with computing services for campus funding. Beyond the infrastructure support, college libraries have also had to absorb the costs of purchasing the content of indexes, online journals or electronic books. Although the annual costs of purchasing the content may replace or at least reduce the costs of building

new space and maintaining print collections, budgeting for electronic resources will continue to be a challenge to college libraries.

Technology has extended its replacement of print resources well beyond indexes and now is on an accelerating pace to replace print periodicals and is making significant inroads in providing electronic books. That electronic texts will replace many print books is not debatable any more; the question now is how quickly and to what degree.

College libraries now face competition from commercial enterprises that offer “libraries” of electronic resources, for a fee, directly to students. Carol Ann Hughes of Questia, one of these commercial enterprises, talks about the “new competitive space,”^[20] pointing out that academic libraries no longer have the exclusive role as the gatherer and supplier of information. If college librarians are to be effective in supporting students’ information needs, they must go well beyond providing space and collections. College libraries must provide, to use the business language of the day, added value to their collections and facilities. Such added value includes reference and instructional services both within the library’s facilities and over the network, which are tailored to the unique needs of course assignments. Convincing the college community of the value of such activities remains the single most important challenge to college libraries. This is not new; it is the perennial challenge of college librarianship now made imperative by the real competition of commercial enterprises such as Questia. [The Questia service is a commercial activity, begun in 1999, which plans to sell access to “libraries of full-text of books and periodicals directly to students at an annual or monthly rate.” More details are available at QuestiaSM—The Revolutionary Online Research Service. Questia Media: n.p.; <http://www.questia.com/what.html> (accessed January 20, 2001).] In so doing, college librarians will demonstrate to administrators their unique contributions to the academic program through curriculum-related collection building, development of enhanced methods for accessing information resources, teaching the use of information resources, and providing personal assistance. The impact of such activities is to enhance the teaching and learning process.

COLLECTION DEVELOPMENT

Collection development in college libraries had long been ignored in the overall collection development literature.^[21] In 1991, Joanne Schneider Hill and her coauthors produced the first book devoted to collection development in college libraries. In their introduction, they noted the strong belief that collection development activity was the same regardless of the size of the library.^[22] Therefore, it was assumed that articles and books about university collection development were applicable to smaller libraries

as well. However, beginning in the late 1970s, perceptions began to change. In her essay, “Collection Development in College and University Libraries: A Comparison,”^[23] Mary Casserly thoroughly vitiate that notion. Her point that college and university libraries are different is consistent with Farber’s university library syndrome concept. The differences fall into two main categories: purpose and organization. The development of college library collections is highly focused on meeting the immediate needs of undergraduates and only secondarily are other audiences and the long-term future taken into account. This focus is illustrated in a sample collection development policy included in ACRL’s CLIP Note #11 on this topic:

...the major responsibility and top priority of the library lies with the teaching programs at the undergraduate level. The library endeavors to serve the needs of the faculty either by purchasing (if the materials can also be used by the student body) or by securing through interlibrary loan those resources needed for faculty study and research. Although at a much lower priority, the library services the entire college community through the purchase of recreational, cultural and general information materials.^[24]

The second difference is in the organizational structure that supports collection development. University libraries often have a separate unit that is responsible for collection development even when there is a broad based liaison relationship of librarians with faculty. The separate unit is seen as critical in managing large budgets and in proactively seeking out material to develop the collection to meet the current and future research needs of faculty and graduate students. In college libraries, there may be one staff member such as the director or an acquisitions or collection development librarian who is responsible for authorizing purchases. However, other librarians, particularly those who work in reference or public services, share responsibilities for developing the collection.

Although the idea that collection development in college libraries should focus on supporting the needs of undergraduates is a broadly shared one, there has been controversy over how the idea might be interpreted and implemented. William Miller and Stephen Rockwood, in a 1979 article, proposed that collection development should be carefully tied to the level of bibliographic instruction activity because that activity is an excellent indicator of library use.^[25] However, Evan Farber, an active supporter of bibliographic instruction, claimed that such a narrow basis for collection development was inappropriate on several counts. It is politically problematic because it makes bibliographic instruction an arbiter of budget allocations and thus appears punitive. More importantly, it focuses “support of the curriculum” too narrowly.^[26] Farber pointed out that bibliographic instruction is not an end in itself. Rather, like all aspects of the library’s program, including collection

development, bibliographic instruction is just one way, albeit a critical way, for the library to support the academic program. There are ways in which the library's collection can support the curriculum without the presence of instruction within a department or major program. Farber pointed to the need to support the curriculum as the basic focus of collection development in college libraries.

Throughout much of the twentieth century, college librarians have explored the notion of a core collection. Hardesty and Mark in "searching for the Holy Grail," reviewed the history of the various attempts to create core lists of titles that were considered to be the most important for or best suited to an undergraduate library. However, their review of overlap studies revealed that college library collections have not developed as though there were such a thing as a core collection. Rather, the overlap studies of consortial groups of libraries found that large portions of college library collections, even in the smallest libraries, were unique.^[27]

As electronic resources developed, college librarians looked to them as a boon for college libraries: they would greatly enhance the availability of resources and "level the playing field" for college libraries relative to university libraries.^[28] However, as the availability of electronic resources has developed, the playing field has not been as level as was hoped because of the high costs, even when there are small library pricing plans. Although there is no doubt that electronic resources have improved access across campus, they are not cheap. In fact, electronic versions of periodical indexes and journals are likely to be more expensive than the print versions or may be an added cost to a required print subscription. Despite that expense, college libraries have acquired electronic resources to improve services and access. To mitigate the high costs of electronic resources, college libraries have either joined state networks (e.g., Galileo, ILLINET),^[29] OhioLink, or formed their own consortia (e.g., PALNI^[30]) to make joint purchases. Although there is no doubt these joint purchases reduce the out-of-pocket costs to individual libraries, such joint purchases add administrative overhead costs such as participation in consortial governance, the group selection processes for databases, and the management of group license agreements and budgeting.^[31]

The development of electronic journal collections has created new entities—block purchases—for college libraries to consider in their collection development. Although many journal titles in electronic format are available individually, publishers have often packaged their periodicals in bundles that require purchase of the entire bundle. These discounted packages greatly benefit large academic and public libraries, but for most college libraries, they are often beyond their financial means, unless purchased consortially. Furthermore, all parts of the package are not items needed to support an undergraduate curriculum.

INTERLIBRARY LOAN

Interlibrary loan may seem a minor service of college libraries and, therefore, undeserving of a separate section. However, those who work in college libraries know that, as a result of a changed view of collection management, as well as economic and technological developments, interlibrary loan is now a central service in college libraries.

Daniel Gore and others foreshadowed the changed view in a 1975 collection of papers entitled *Farewell to Alexandria: Solutions to Space, Growth, and Performance Problems of Libraries*.^[32] Throughout the essays, but particularly in Gore's essay of the same title,^[33] the idea is presented that if libraries would continue to grow exponentially as they had in the previous three decades, costs of major space and building needs and their attendant costs would be prohibitive. Instead, libraries and their users needed to develop a new view of the role of libraries. That new view was of college library collections as working collections designed to meet the immediate needs of the curriculum,^[34] with the complimentary development of services that provide access to those materials, which are occasionally needed. Therefore, the role of interlibrary loan became more important in college libraries. College libraries, whether they subscribed to Gore's "zero-growth" concept or not, were forced to curtail their purchasing because of the inflation in the cost of library materials in the 1970s and 1980s, especially periodicals,^[35] and the cost of construction. Concurrently, college librarians came to realize that their libraries could better serve patrons with a smaller carefully selected collection.^[36] Also, as Karen Liston Newsome pointed out, improved bibliographic access and the automated request systems through such services as OCLC greatly facilitated increased use of interlibrary loan.^[37] In the early 1990s, the availability of electronic databases led to an increase in the use of interlibrary loan.^[38] Together, the change in the focus of collection development, the growing costs of library materials, and the application of technology to interlibrary loan, increased the use of interlibrary loan in college libraries.

This increase in the use of interlibrary loan is dramatically illustrated in data from a group of Midwest liberal arts colleges.^[39] Over a 20-year period, 1977–1997, lending increased 980%, and borrowing increased 703% (Table 1).

Table 1 Interlibrary loan activity in a selected group of Midwest liberal arts colleges.

	1977– 1978	1982– 1983	1987– 1988	1992– 1993	1997– 1998
Lent	557	840	1798	2696	6025
Borrowed	852	1001	2101	2622	6844

Although the volume of interlibrary loans borrowed by this group grew dramatically, the number of items lent increased more rapidly. Other reports^[40] also showed that college libraries were lending at least as many items as they borrowed and in many cases more. College libraries had become full partners in the national interlibrary loan system, and not as some had predicted, raiders of the collections of larger libraries.

User-initiated interlibrary loan has moved from a possibility to a reality. OCLC's FirstSearch now provides users of their databases with the capacity to initiate an interlibrary loan through the OCLC system.^[41] Furthermore, in consortia such as OhioLink, the users can request items directly from member libraries without making the request personally to a local library staff member. This practice has significantly increased the volume of interlibrary borrowing while reducing the volume of material processed through the traditional OCLC system.^[42] User-initiated interlibrary loan request are another example of how technology can increase access while reducing unit costs. At the same time, by making requests for loans so easy, the volume of requests may increase and intensifies the need for library users to be more effective and thoughtful users. Some, if not many, college reference librarians have regarded their interactions with students about interlibrary loan requests as "teachable moments" (i.e., occasions to talk over with students their requests). Although such encounters obviate the rapid access and lower cost that technology can provide, the elimination of individual consultation increases the importance of teaching students to evaluate resources and effectively use the local collection before the self-initiated interlibrary loan events occur.^[43]

BIBLIOGRAPHIC INSTRUCTION/INFORMATION LITERACY

Perhaps the most significant programmatic change in college libraries has been the development and main streaming of instructional programs. Such programs take many forms, but they all share a common focus: providing students with skills that both help them complete assignments in their courses more effectively and help prepare them for a life of self-directed learning. Such goals serve both the practical short-term needs of students and the long-term goals of an undergraduate education.

Mark Tucker has provided a history of instruction in academic libraries prior to the early 1960s.^[44] In that history, Tucker focuses primarily on developments in university libraries. The one exception was the Library-College movement, which began in 1928 and continued into the late 1960s. The history of the concept was told in 1966 in the last major publication on the idea.^[45] The Library-College idea was to integrate the library into the curriculum so that the library becomes the college,

melding classroom teachers and librarianship.^[46] The concept questions the traditional structure of college personnel by requiring staffing with individuals who do not have the background and training of traditional graduate and professional education. Because of this incongruity, the concept only gained a temporary foothold in a few institutions where the administration could mold the structure of the faculty and the library to approximate what is needed to realize the concept. The idea never survived beyond the few initial implementation efforts.

Despite the failure of the Library-College movement to change the relationships of teaching faculty and librarians, the movement did introduce a new idea to the library profession. Patricia B. Knapp, without mentioning the Library-College concept or the name Louis Shores, the movement's foremost promoter, used the exploration of "methods of developing more vital relationships between the library and college teaching"^[47] in her Monteith College project in the early 1960s. Knapp's contributions were cut short by her untimely death in 1972.^[48] Nevertheless, her work had a significant impact on the development of bibliographic instruction in college libraries by demonstrating the effectiveness of course-related and course-integrated approaches.

At about the time of the Monteith College experiment, another institution, Earlham College, was beginning to experiment with the concept of course-related instruction. Evan Ira Farber was appointed college librarian at Earlham in 1962 and almost immediately recognized the need for instruction to help students with their course assignments.^[49] As Thomas Cottle described the institution in the early 1970s, Earlham gave unusual attention to a range of general education goals, which included preparation for a life of self-directed learning.^[50] In this fertile ground, Farber developed a program that would become a model^[51-53] that continues to this day.^[54] Patricia Breivik writing about the Earlham program says:

Basic to this entire program—to its integration, its structure and its extensiveness—is a close working relationship between librarians and teaching faculty in planning and implementing library instruction.^[55]

This model of close working relationships between librarians and teaching faculty was recognized by librarians such as Breivik as key to the successful incorporation of the library into the academic program, and many sought to explore means to overcome the inherent barriers that the Library-College concept had not overcome. In response, Earlham conducted a number of workshops from the early 1970s to 1995—workshops that gave librarians and faculty an opportunity to examine the Earlham model and to explore how they might build these critical working relationships in their own institutions.^[56]

The decade of the 1970s was the golden age of bibliographic instruction in college libraries. In addition to

Earlham's developing program, the Council on Library Resources (CLR) funded 51 projects (36 of them with assistance from the National Endowment for the Humanities) in an effort to support "experimental endeavors to improve the relationship between libraries and faculty."^[57] The 51 institutions were predominantly undergraduate institutions, and 35 of those were small liberal arts colleges. This infusion of funding into experiments in library programming designed to enhance the role of libraries in academic programs generated a smorgasbord of examples on which college librarians feasted over the next decade. A bibliography of the publications describing the outcomes of these projects is available in Nancy Gwinn's 1980 review of the CLR programs.^[57]

With the increased availability of electronic resources and on-line tools for massaging information, new ideas changed the scope of instruction. Lori Arp^[58] and Loanne Snaveley and Natasha Cooper^[59] have reviewed the semantics, the conceptual dimensions, and the politics of the shift. Over the course of the twentieth century, the terms orientation, library instruction, bibliographic instruction, and information literacy have been used. In succession, the proponents of each new term have claimed the new term is more encompassing and better frames the concept of teaching the use of information resources in relation to the other aspects of the liberal arts. In each case, the new concept is seen as encompassing all previous concepts. For example, bibliographic instruction was seen as including the former content of library instruction, while adding the notion that the instruction should be focused on a broader set of ideas than just how to use a particular library. The scope of the enterprise has been conceptualized in still broader terms, and the responsibilities of librarians have expanded. Jeremy J. Shapiro and Shelley K. Hughes define this expanded scope when they wrote that:

... information literacy should in fact be conceived more broadly as a new liberal art that extends from knowing how to use computers and access information to critical reflection on the nature of information itself, its technical infrastructure, and its social, cultural and even philosophical context and impact—as essential to the mental framework of the educated information-age citizen as the trivium of basic liberal arts (grammar, logic and rhetoric) was to the educated person in medieval society.^[60]

The implication is that information literacy is not just the responsibility of librarians; it is the responsibility of the entire faculty and the institution.

In response to this change in the concept in the 1990s, the Andrew Mellon Foundation began awarding grants to colleges that, as the CLR grants of the 1970s did, bring librarians, faculty, and the new partner, instructional technologists—those who focus on the application of technology to educational activities—together to develop model programs.^[61]

Despite the changing terminology and the expanded scope driven by technology, the critical dynamic remains the working relationship of librarians and classroom faculty. Evan Farber points to this similarity in "Plus Ça Change..."^[13]

COLLEGE LIBRARY STANDARDS AND CHANGES IN ASSESSMENT AND ACCREDITATION PROCESSES

College library standards were first promulgated in 1959 by the Association of College and Research Libraries for the purpose of providing "...a guide for the evaluation of libraries in American colleges and universities which emphasize four-year undergraduate instruction..."^[62] During the 41 years since then, there have been four revisions, in 1975, 1986, 1995, and 2000. The standards have continued to provide a guide for evaluation despite the changes in the assumptions on which they were founded and the resultant changes in content. The changes in standards can help one understand the changing assumptions about what is most important in assessing a library's quality.

The 1959 standards are in the form of a series of prescriptive statements on the appropriate characteristics of a college library. These are grouped in seven categories: functions, structure and government, budget, staff, collections, building, quality of service and its evaluation, and interlibrary cooperation. The statements of characteristics were written in general terms; for example, in the statement on collections: "The collections should meet the full curricular needs of undergraduate students and should be easily accessible to them."^[62] There were only a few quantitative measures such as staff work space (125 square feet per person) and collection size (minimum of 50,000 volumes and 10,000 volumes for each 200 additional students over 600).^[62]

Not until 1975 did a new set of standards appear.^[63] Although "should" was changed to "shall" and there were other minor changes in language, the major changes were the addition of "commentary" and quantitative standards. Organized under eight categories (objectives, collections, organization of materials, staff, delivery of service, facilities, administration and budget) each standard has appended "a brief explanatory exegesis...citing the reasons for its inclusion and providing suggestions and comments upon its implementation."^[63] This "commentary" appears to be a reaction to the vagueness of the 1959 standards. The intention of the authors seemed to be to provide some guidance about implementation through specific suggestions.

The second major change was the addition of quantitative measures for collection, staff, building, and budget size. In each case, a formulaic approach was developed that took into account the size of the institution and the

scope of the curriculum. By using these formulas, it was deemed possible to provide some objective evidence of library quality and minimum. It was further hoped that by providing a basis for comparison among college libraries, poorly supported libraries would have the data to argue for enhanced resources. In fact, the writers went so far as to assign grades (A, B, C, D, and unacceptable) to various levels of achievement for each quantitative standard.^[63]

The 1986 and 1995 revisions of the standards^[64,65] resulted in little substantial change, despite serious questions raised by Ray Carpenter^[67] who analyzed how well—actually how poorly—libraries performed relative to the standards, and despite a growing body of literature that pointed to performance measures as a more appropriate mechanism for assessing the quality of libraries. Nevertheless, the formulas for collections, staffing, building, and budget were left the same. Revisions in the language of the standards and the commentaries were updated in the 1986 edition to better account for nonprint collections and services and networking and cooperative activities, but the overall structure was left intact.^[64]

The introduction to the 1995 standards noted the rapid changes in technology and acknowledged that although more technological developments would have significant impact on library operations, it “will take about thirty years” for libraries to really respond to advances in technology.^[65] Thus, they left it to the next generation of revisors to incorporate technology into the standards.

Even before the 1995 standards were written, Ronald Leach had called for academic librarians to focus more on outcomes as an indicator of quality in academic libraries.^[67] The increasing recognition of outcomes as an indicator of quality led the Association of College and Research Libraries to establish a Task Force on Academic Library Outcomes Assessment in 1998. In its report, the task force went to some length to distinguish among inputs, outputs, and outcomes. With these three different ways of looking at library performance in mind, the task force concluded:

...that standards should be based on evidence of normative practice or...programmatic success as determined by the measurement of outcomes. ...Wherever possible, inputs should be related to and support desired outcomes, rather than vice-versa.^[68]

One recommendation of that report was that ACRL should revise its library standards; as a result, the College Library Section's Standards Committee took the initiative to write the first ACRL set of standards that used the tripartite concepts of inputs, outputs, and outcomes as the paradigm. The 2000 edition of the Standards for College Libraries^[69] has sections not unlike the earlier editions, but it also has newly titled sections that reflect a focus on services and activities (e.g., instruction, and access). The 2000 edition includes a series of “should” statements, not

unlike those of the 1959 standards, but each of these statements is followed by a series of questions that give definition and specificity to the “should.” In the 2000 standards, the quantitative standards were removed, and a new section was added on “Planning, Assessment and Outcomes Assessment.” The new standards do not reject input measurements as part of the assessment process. Rather, they suggest a combination of measures. One measure is based on ratios that take into account an institution's size (e.g., acquisitions expenditures per student). A second measure examines outputs and outcomes.

The ACRL Standards are the principal means by which librarians have measured quality in college libraries, but for the regional accrediting agencies, the quality of college libraries is measured through a set of standards that are less specific and placed in the context of the larger institution. Despite the differences, according to Paul Coleman and Ada D. Jarred's analysis, the assessment criteria for libraries in five regional accrediting associations' standard focused on issues similar to those in the 1986 Standards for College Libraries, although the ACRL Standards are more quantitative.^[70]

As Coleman and Jarred acknowledge, the accreditation standards go beyond the measurement of inputs to focus on output measures. It appears that in the 2000 revision of the Standards, ACRL was trying to catch up with the regional accrediting associations' emphasis on output and outcome assessment.

As this entry was being written, some accrediting agencies were in the process of revising their criteria for accreditation. The changes continued to move further in the direction of outcomes by framing the criteria in student learning. As Jane Wellmen, senior associate of the Institute for Higher Education Policy, pointed out, “Learning outcomes assessments have been a long time coming and are, in many ways, a welcome and necessary change.”^[71] However in over emphasizing them at the expense of basic measures of resources available (e.g., size of faculty, size of library collection, and amount of time spent in class), Wellmen fears that assessment of learning outcomes that best serves the internal development of the institution is too narrow a gauge of quality for the external world of the larger society. Through input measures an institution is better able to demonstrate the resources that are needed to strengthen the institution. Furthermore, not everything in an institution should be viewed through the lens of student outcomes. For example, it would be futile to try to assess the quality of a library facility through the level of student learning because of the indirectness of the connection between student performance and quality of facilities and the number of mitigating factors such as number of library assignments and the quality of information literacy program.

In the fall of 2000, the Accreditation Review Project of the Commission on Colleges, an arm of the Southern Association of Colleges and Schools (SACS) illustrates

another problematic trend in library assessment. In an effort to create a performance assessment statement that encompass all types of service deployment—traditional building based library and virtual electronic collections—the standards statement is written in the most general terms. In the draft “Principles and Requirements for Accreditation” issued in September 2000 for membership comment, the criteria for library services are stated as follows:

Core Requirement Related to Learning Resources

The institution provides and supports student and faculty access and user privileges to adequate learning and information resources which are consistent with the degrees offered and are sufficient to support all educational, research and public service programs (*Core Requirement#9*).^[72]

This statement is not only vague but begs the question of what is a quality library. Furthermore, the statement lacks any interest in the college library’s educational role beyond supplying sufficient resources. The efforts to measure effectiveness in outcomes and to describe adequacy in the most general terms—sufficiency to meet program needs—tend to confuse those interested in understanding the characteristics of a quality college library.

LIBRARY MANAGEMENT, STRUCTURE, AND STAFF CHANGES

A number of factors have had and will continue to have a profound impact on the staffing of college libraries: the changing nature of assessment and accreditation, economics, the increased use of technology, the declining supply of librarians, and the expanding mission of libraries. This impact is evident at every level of the college library staff—student employees, paraprofessionals, librarians, and library managers—as well as the organization as a whole.

A series of articles have appeared on the roles, responsibilities, and management of student employees^[73–75] and paraprofessionals.^[76] The increased sophistication in their work is the result of the increased use of technology and the shift in work tasks of librarians to instructional programming and management of technology. These articles identify the increasing complexity of their work and the resultant need for more training.

Although many aspects of college library organization have gotten considerable attention, the relationship between computing and the library has probably gotten more attention than any other. In an early article, Guskin et al. concluded the library is the appropriate part of the academic institution to take on the responsibility for helping institutions use microcomputers and their applications software effectively in their educational programs.^[77]

That was a prescient comment, and a number of libraries followed that advice. But most did not, and the relationships between the two units varied greatly. In 1997, Larry Hardesty studied the variety of organizational relationships between computing and the library which developed in the absence of any consensus about the college library’s role vis-a-vis computing. He concluded:

Libraries and computer centers face similar challenges. . . . Nevertheless, no organizational structure will solve all, or even most, of these challenges. . . . We must define carefully the problems we seek to solve and consider individual and group differences before hastening to solutions that may prove to be only temporarily fashionable.^[78]

Hardesty’s conclusion that situational factors should dictate organizational structure is a wise one. It suggests that the preferred structure should not be some imposed ideal but rather the one that best addresses the library’s needs.

The challenges of adequately preparing leaders for college libraries has been a concern of the profession,^[79] and in response, under the leadership of Larry Hardesty, the Association of College & Research Libraries’ College Library Section has conducted the College Library Directors Mentor Program since 1992.^[80] This program provides each newly appointed novice director with a mentor, an experienced college library director, with whom she or he could consult; after a few months all first-year directors—15 or so a year—attend a workshop that explores commonly faced issues and approaches to addressing them. This program has become increasingly important as young and less experienced librarians become directors to fill the increasing number of open leadership positions caused by retirements.

CONCLUSION

College libraries, through a combination of forces have made unprecedented strides in the development of access to information resources and in offering services to help students and faculty make greater use of these resources. In so doing, college libraries have become more critical to the success of the host institution. They are now poised to build on the advancements of the past 30 years to respond to the environmental changes and user expectations and to meet the challenges of being even more integral to the academic program.

The authors of the 1995 Standards for College Libraries, beginning to feel the impact of technology, indicated that it would be 30 years before the full impact of technology would be realized in the operation and use of college libraries. What was more likely is that in the 1990s college libraries entered a new world in which *change* is permanent. College libraries will be constantly

adapting to changes in technology, curriculum, economic health of the host institutions, and to the nature of the profession. One doesn't even know if "library" as we know it today will still exist on college campuses. The new forms of competition developed by commercial interests and delivered over the internet could supplant the concept of the library as a physical space and a source of expert advice in using information resources. The ultimate challenge for college libraries is to deliver, at a high level of quality, those services and facilities that are unique and cannot be provided by others. To do that, the following is needed:

1. An adequately trained staff who not only know the traditional technical skills of librarianship but are also effective teachers and collaborators with classroom faculty and other academic professionals.
2. An effective alliance of computing services and the library so that adequate technology can be deployed.
3. A strong program of information literacy/bibliographic instruction that assists students in effectively using information resources for course work and provides them with the skills and attitudes to be effective life-long learners.
4. A balanced approach to collection development and programs of access that maximize the availability of needed information resources within a constrained budget.
5. An active program that both markets the library's services to the community and listens and responds to community needs.

Communication and Communication Studies

Brenda Dervin

School of Communication, Ohio State University, Columbus, Ohio, U.S.A.

CarrieLynn D. Reinhard

Department of Communication, Business, and Information Technologies, Roskilde University, Roskilde, Denmark

Abstract

The focal purpose of this entry is to lay out the contours, within historical contexts, of the structural arrangements and intellectual foci of the various areas of study and emphases in institutions of higher education generally clustered under the much used and abused term “communication.” Because communication studies has been a presence in the academy for less than 60 years, and because it has evolved in the midst of an exploding and rapidly changing communication environment, there are necessarily multiple and competing stories to be told. This entry attempts to focus both on convergences and divergences. The entry reviews in turn: different meanings for the word “communication” and how and when the term came into popular usage; the two primary historical lineages out of which communication studies has emerged—speech communication and mass communication; the forces leading to institutionalization, including the exploding emergence of mass media. The entry examines the phases in which communication studies became institutionalized and how supporting structures of organizations and journals have handled seemingly overwhelming diversity. The entry concludes with a discussion of how communication studies necessarily holds within its core a series of contradictions that are in essence symptom and cause of both centralities and dispersions, struggles and successes.

INTRODUCTION

Communication is a much used and abused term. In everyday parlance, it most often refers to humans sharing experiences, ideas, and feelings with each other via some kind of verbal or nonverbal symbolic language, including words, gestures, body language, tonality, and nonverbal expressions. Sometimes this sharing is done in person; sometimes over an increasingly wide variety of mediated means, across stretches of time and space. Sometimes the sharing is one person to one; sometimes one to many; sometimes many to many.^[1–3]

Much emphasis is placed in our society on improving communication. At one and the same time it is felt that improved communication will make each of us more successful at persuading others; and simultaneously help us get along better with each other within and between families, groups, organizations, and nations. Good communication is expected to help us to be better informed and more knowledgeable, increase both human happiness and effectiveness, and facilitate justice, democracy, and peace. Communication is assumed to be a fundamental and essential social process.^[2,4] Much is asked of a phenomenon about which there are, when one digs below the surfaces, an extraordinary number of differing and competing definitions, theories and expectations of what role communication does, could, or should play in human affairs.^[2,5–14]

It is not known who first used the word “communication.” The term itself is visibly identifiable in a variety of forms in biblical and philosophic writings in the fourteenth century. But, before that in the first century B.C., the ancient Greeks focused on concerns for effective communication with their emphases on rhetoric and oratory. Throughout the ages, tales focusing in some way on communication have appeared in literature, folklore, poetry, and religious treatises. One famous example is Persian Omar Khayyam’s Rubaiyat in which concerns for communication between leaders and the people are a frequent focus. Another is the Anansi myth, a generative base for numerous tales that originated in West Africa and spread via imposed slavery and diasporic immigration of African communities throughout the globe.^[15–19]

It is fair to say that communication has been a fundamental concern for the human species since antiquity.^[16,19] Yet, the appearance of institutionalized emphases labeled communication via academic courses and programs did not begin to appear until the late 1930s and 1940s. The appearance of these emphases emerged from a convergence of long journeys from disparate origins with sometimes incommensurate understandings. Major players in the story have journeyed from such diverse fields as anthropology, education, engineering, literature, family life, linguistics, literature, government, philosophy, political science, psychology, rhetoric, semantics, semiotics, sociology, and written and oral

composition.^[5,15–17,20–25] The result has become an array of institutional arrangements that still, despite some 70-plus years of development, appears chaotic both to outside and inside observers.

The story of communication must be told in a way that allows this chaos to remain apparent while making some sense of what must be called an extraordinary revolution in scholarly attention—a revolution that moved us from a time when no academic unit admitted to focusing on communication to a time when communication has become virtually everyone's concern with emphases on communication spread throughout virtually every academic institution. At the same time, the story must be told in a way that allows not only the divergences and differences to show but centralities as well. Particularly important is the centrality of what for many in communication studies, including most of the notable founders, is more than merely an intellectual focus but a passion for and a vision of what difference it would make to look at humans and their institutions, cultures, communities, nations, and societies through a new kind of lens. This lens, a communication lens, focuses not on separate habit-driven entities, as the common conception of human beings and their collectivities comes to us from psychology, sociology, and anthropology, but on how these entities use communication to forge the human experience in the constantly changing and often chaotic conditions that constitute the contexts within which humans live.^[8,14,27–29]

Finally, because communication studies, as a relatively recent arrival on the academic scene, has struggled with self-definition and with self-defense in often rigid academic hierarchies, there has been an extraordinary self-consciousness in the field resulting in a plethora of self-examining articles.^[5,7,9,11,12,14,27,30] The literature is large, disparate, and incomplete.^[5,20] References in this entry must be understood as illustrative rather than comprehensive. This entry limits specific details to the U.S. context although the available histories suggest that the impelling forces and consequences have been much the same worldwide except for how specific cultural environments have changed qualitative emphases in each national, regional, and cultural context.^[5,15,17,22–24] Brief examples will be given of these differences but the story as told here applies primarily to the United States.

The presentation of the varying stories of communication and communication studies is presented below in six sections: 1) meanings for the word “communication” and how these anchor on a common core but also vary markedly; 2) two primary institutions that became the sites of communication studies—speech and mass communication; 3) the exploding emergence of media; 4) the phases of the institutionalization; 5) structures for handling the diversity; 6) communication studies and its productive tensions.

The narrative is organized around a presentation that examines: 1) how emerging societal attentions to something

called communication, particularly as sparked by the exploding diffusion of mass media, led to two streams of communication studies, one based in ancient humanistic studies of rhetoric; the other focusing on the scientific study of media; 2) how these different streams have moved toward each other while retaining their historical characters; and 3) how communication studies in general manages the necessary diversities of attention imposed by the fact that communication—the phenomena of interest—always occurs in particular contexts with distinctive attributes.

Meanings for the Word “Communication”

Purpose in this section is to examine the emergence of the term “communication” and how it was put on policy and popular agendas, and ultimately, academic agendas. The second purpose is to survey the various definitions applied to the term, focusing on both a common core while exhibiting the many divergences.

While the species has addressed concerns about communication since ancient times, early systematic attentions were limited to the study and practice of rhetoric as artful oratory in public and institutional settings.^[5,15–17,26] Below the surfaces of these systematic attentions there were the ruminations of poets, storytellers, and religious leaders capturing what they saw as wisdoms for understanding essential struggles of human existence—the problems of getting along even within relatively homogenous enclaves and temporally and geographically confined boundaries.^[18,19] The varying uses of the term communication as we know them today did not begin to emerge until advances in technology permitted mass production of messages and the transmission of these messages across time and space. The term first drew large-scale attention in policy debates and in popular imagination. These attentions were impelled by the exploding diffusion of mass media in the first half of the twentieth century as well as by the increased struggles to gain public space in which to be heard by diverse populations worldwide. It was these attentions and events that made the institutionalization of academic studies in communication possible.^[5,16,17,20,26,31]

Most definitions of communication have a common core although this common core goes beyond the “sharing” focus that dominates popular usage. Definitions focus on sharing but also relaying, transmitting, imparting, or exchanging in some way a message or messages of some kind via some means from one or more entities to one or more other entities in some context. The entities to which this core definition of communication has been applied have included not only human beings and their various collectivities and symbolic artifacts, but also other living animals as well as nonliving entities such as radio systems and railroads.^[1–3,5,20,23]

The last point deserves special emphasis because, in fact, the emergence of communication as a term in the

English language between the late 1700s and the late 1970s was as likely to focus on communication as linkages between humans as to refer to connecting passages, sea channels, railroads, electrical transmissions, and other technological and natural avenues that permitted movement across space and time.^[5,20] When the term referred to human communication, it was as likely to imply a view of humans as transmitting senders and receivers as it was to focus on humans relating, sharing, or exchanging with each other. Further, it was as likely to refer to communication as instrumental manipulation and persuasion as it was to engendering mutual understandings. It was rarely used to refer to something now called intrapersonal communication—self communicating with oneself across time and space.^[8,14],28]

Some observers suggest that the tensions between these branches of emphasis still mark communication studies today.^[5,11,12,20] Some have argued that the U.S. emphasis on instrumental communication that dominated communication studies from the 1950s through 1980s was an unconsciously adopted preference for meanings that reflected the instrumental ideologies that had dominated the very character of U.S. expansion.^[10,13,20,23] Some have charged that this hidden hegemony is one cause of why histories of communication study and its emphases vary sometimes quite markedly between portraits emphasizing instrumental values and those emphasizing humanistic values. These issues remain among the many enduring debates in communication studies. In particular, there remain concerns about whether or not conceptualizing human beings as if they are transmitters and receivers is useful for understanding the role communication plays in the human condition.

When the core definitions above are applied specifically to human communication, on the surface at least the definitions seem to have much in common. One simple and common definition of communication is “how people use messages to exchange meaning.”^[1] From this simple core, one finds a large variety of definitions that bring in more and more aspects of the phenomena as the definers see it. Two typical more complex definitions might read as follows: how people use messages to generate meaning within and across contexts, cultures, channels, and media; or, the processes by which people inform, persuade, manage, relate to, and influence via channels and media through contexts and culture.^[2,3]

As will be shown below, within these seemingly congruent definitions, those doing communication studies have launched upon a dizzying array of topics, theories, models, and approaches. Most of the differences are accountable in terms of how different researchers have chosen to focus on different goals, contexts, levels of analysis, and so on. We find, for example, different scholars defining communication in ways useful to the study of communication: 1) at different levels of social analysis, e.g., interpersonally, intergenerationally,

cross-culturally, internationally; 2) in different content or knowledge domain applications, e.g., health, politics, democracy, marriage; 3) in terms of the goals they see communication serving, e.g., persuasion, negotiation, dialogue; or, 4) in terms of how communication serves and impacts different socially defined groups, for example, women, minorities, disabled, gays, and lesbians. These are but examples for the differences are many.^[3,5,32–34] The differences can be seen as details on which the study of communication must be based. Yet, communication studies must also bracket the differences in order to look at communicative essences.

It is important to note, however, there are more subtle variations that mark attempts to define communication. Various authors have identified these in different ways and many different words are used for the relaying, transmitting, imparting, sharing, or exchanging that seems central to all definitions. To illustrate these variations, consider the word relaying. Cutting across the differences, it can be said that definitions of communication and implementations of these definitions focus on communication as: 1) behavior: the act of relaying; 2) codes: the languages and symbolic systems used in the relaying; 3) information: the contents that are being relayed; 4) message: the package in which the contents are wrapped so they can be relayed; 5) means: the channel, media, or system through which the message is relayed; 6) skills and techniques: the relaying practices and procedures; 7) process: the steps involved in the relaying across time-space; 8) meanings: interpretations of the message as understood by those involved in the relaying; and 9) outcomes: impacts of the relaying, often an assessment of whether the relaying was successful.^[5]

These subtle differences in definitional emphasis make a great deal of difference when it comes to understanding what is being addressed. Take, for example, the difference between a definition that focuses on communication as process versus one focusing on it as outcome. For the latter, communication is an end point, it comes after the relaying. For the former, it is the very process of relaying itself. As another example, compare a definition focusing on information with an external authoritative representation of message content versus one focusing on meanings where interpretation occurs within a person or cultural context. The mischief caused by these differences is, understandably, the subject of enduring debates in communication studies.

Two Primary Institutions—Speech and Mass Communication

As will be shown below, communication as a focus of study eventually spread into every nook and cranny of the academy. However, the history of the institutionalization of communication studies has been essentially the story of two major emerging structural arrangements. One focus

has become today's emphases on mass communication, broadcasting, and journalism; media studies; advertising and public relations; communication and information technology; and communication law, policy, and economics. The other focus has become emphases on speech, rhetoric, debate, argumentation, and oral interpretation; communication codes; interpersonal and intercultural communication; group, organizational, network communication, and, sometimes, speech and hearing science. These basic categories of attention in the two root structures can be found in varying combinations across academic units. The two root structures are themselves most often referred to as mass communication and speech communication.^[9,16,17,21,23,25,31,35]

In today's academia, many units still reflect these historical divisions, although rarely as cleanly as suggested above. Further, when one sees a unit named simply communication, that unit will usually be reflective of one or the other of these lineages. Sometimes one finds a comprehensive or unified unit that cuts across the lineages. In the United States, these are more likely to be found at second tier and teaching-oriented institutions. In top tier universities, the lineages often remain divided even to the extent that sometimes the media-oriented unit will be located in a social sciences college while the speech-oriented unit will be in a college of humanities. When one looks at the two major journeys that constituted the advance of communication studies—that of mass and speech communication—it becomes possible to understand why to this date the histories of the field and descriptions of its emphases show great diversity and competing narratives.

The mass communication journey involved the introduction of new, modern emphases on artifacts with relatively recent introductions—newspapers, radio, film, telephones, television, digital games, and the Internet. In a relatively short span of time, new media units were introduced from one end of the country to the other in academia first with a focus on skills trainings and not long after in order to understand the rise and role of media in people's lives and society at large.^[5,17,23,26]

In contrast, the speech communication journey arose from its ancient legacy focusing on rhetoric, dialogue, discussion, argumentation, and oratory. It involved absorbing into traditionally anchored and agreed upon discourses entirely new emphases, focusing, for example on: fostering long distance romantic partnerships, improving intercultural communication for transnational corporations, managing organizational knowledge production and memory. The rise of newer media such as e-mail, video-conferencing, and virtual worlds began to blur the lines between what was traditionally seen as in person versus mediated communication. Speech-oriented units quickly turned their attentions to these developments.^[5,16,20,21]

Today, as the media landscape of society still rapidly changes, communication-labeled units in the academy

continue to evolve. Some disappear. Some reappear. Some combine, voluntarily or by administrative mandate. Most find ways to collaborate and share resources. Most acknowledge that despite their different origins, today they have common interests.

Other important polarities have stood as barriers between the two root structures. These are reviewed below. For purposes here, the important point is that during the first 30 years of the formal emergence of institutionalized academic units carrying the communication label, the two emergent institutional forms—mass and speech communication—evolved in relative isolation and sometimes mutual ignorance, even though many of the same forces were impacting both.

Given these divergent paths, it is small wonder that these isolated journeys resulted in competing narratives of communication studies—what it is, where it came from, and why. Amid rapidly changing conditions, there has been little time for building historical consciousness.^[5,16,20] Historical descriptions are still sparse and incomplete. Even on fundamentals such as the identification of the presumed founding heroes, the histories tell different stories. In the arena of studies now identified as mass communication, an often named founder is Wilbur Schramm;^[5,17,25] in studies now identified as speech communication, Kenneth Burke.^[5,16] When one adds to the mix founding heroes in communication studies in other parts of the world, different heroes are eulogized.^[5,22–25] In Canadian communication studies, for example, they point to Harold Innis and Marshall McLuhan; in Europe, again as examples, Raymond Williams or Jurgen Habermas. Each arena within communication studies has developed its own isolated history, often presented as “the” history. Founding fathers have only recently been identified as shared across these terrains.

Comprehensive histories only began to emerge in the late 1990s and early 2000s.^[5,20] Communication studies must still realistically, then, be seen as a meeting place where diverse roads have converged out of a plethora of different and rapidly changing labels, sponsorships, leadership goals, and resistances.^[5] There are agreements on central visions and important debates. Even now, however, these can be hard to see through a sea of competing, sometimes contesting details.

Unlike many older traditional fields—e.g., library science, mathematics, philosophy—communication as a field of study exploded onto the scene in our recent modern era, an era characterized by rapidly diffusing media technologies; the uses and abuses of these media for propaganda, publicity, and play; two devastating world wars; the fall of colonial powers; the rise of populist movements; and increasing global connectivity. Simultaneously, there occurred a rising interest in using the emerging social sciences as scholarly approaches to understanding humans and their societies. Part of this surge of interest involved a concern for using the increasing body of social science

knowledge to create better individuals, citizens, and societies. Better was variously defined in terms of values within specific cultural and political-economic contexts. The confluence of these forces meant that governmental agencies and educators worldwide were increasingly concerned about both the potentials of media for what they defined as positive change (e.g., education, literacy, modernization) as well as negative (e.g., injurious propaganda, the spreading of base values, the potentials of mob rule). They turned to the academy for help.^[5,15–17,26,31]

At the same time, an intellectual ferment was brewing that did not fully erupt to impact communication studies in the United States until the 1980s but accounts for some of the differences in how communication is defined, studied, and historicized. This ferment involved collisions between scientific and humanistic ways of conducting scholarship focused on humans and their societies. There were two important trajectories here. One was that studies of media were being introduced in the United States primarily as scientific study while studies of speech had been traditionally anchored in the humanities. During the institutionalizing process, speech-oriented units had no choice but to absorb the social sciences.^[5,16] But, speech communication units were more likely to retain the humanistic traditions as well. This proved over the years another source of debates as the emerging institutional streams were forced to pay attention to each other.

Simultaneously, philosophic thinking about humans and their societies was burgeoning, riding on the surge of interest in the writings of such thinkers as Cooley, Darwin, Dewey, Freud, Marx, Mead, Simmel, Park, and Weber.^[523,25] Most of these writings directly addressed communication-pertinent topics and were fertile sources of ideas about communicating drawn on heavily, but quite differently, in the writings of the various founders of the emerging communication units. These philosophic writings are seen by some as part of a worldwide thrust of attention away from focusing only on individual humans and human collectivities as static entities toward focusing on communication as a lens for examining and understanding human conditions and the communicative forces that constrain or enable human life. In this framework, communication is seen as explanatory of how humans and their collectivities become, rigidify, and/or change.^[8,14,27–29]

Uses of these writers' works were sometimes anchored in stereotypical positivistic or instrumental orientations, focused especially on using scholarship to change people and societies for the better. Others focused on stereotypical humanistic or romanticist orientations, focusing on understanding and nurturing creativity, expressiveness, and human fulfillment. Numerous debates emerged within and between the social sciences and the humanities. In general, because of their differing lineages, United States, speech-oriented communication studies was more open to these debates while media-oriented studies were less so.

In contrast, in Europe and Canada, as examples of regional differences, there was earlier and far more robust attention to these differences.^[22–24] Ultimately by the mid-1980s, these debates became a top agenda item in both mass and speech communication units for at least the next decade—a period sometimes labeled as a time of “ferment in the field.”^[5,9] The debates still continue today, albeit in a more quiescent form.

The Exploding Emergence of Media

There is essential agreement about the importance in the histories of communication studies of the spread of the media and the impacts of this spread on personal, political, economic, and other societal arrangements. Media made it possible to communicate faster across time and space and reach geographically disparate populations. Further, messages came to have a more durable presence in material form. This explosion of changes led to governmental and policy attentions and, hence, academic attention. In the context of the current speed of the diffusion of the Internet, it is difficult to remember that each of the mass media diffused at speeds considered astonishing in their times. This was as true for books, newspapers, telephones, and radios as it has been for televisions, videotape recorders, personal computers, and Internet use.

Gutenberg's invention of the printing press around 1440 is seen by many as the first small step in the rise of mass media. The period between its invention and the 1800s was marked primarily by small scale uses serving the needs of religious and educated elite. By 1800, further technological advances introduced by the industrial revolution made large and inexpensive runs possible both for religious and secular works. In the early 1800s, one found massive runs of Bibles both in the United States and Europe. In 1836, Dicken's *Pickwick Papers* became the first wildly popular novel, a business enterprise unto itself with attached theatrical performances, bootleg copies, and merchandizing.^[5,17,19,26,31,36]

As the book became a tool of mass communication, newspapers were moving forward on their own fast-moving course, showing the same movement from elitist defined contents and formats to more popularized approaches incorporating illustrations, games, comics, and news of popular culture and celebrities. The first newspapers are said to have been circulated in both the United States and Europe in the late 1600s and early 1700s. By the early 1850s, there were some 2500; by the late 1800s, some 11,000. A downward trend in newspaper circulation is attributed to the impact of electronic media. Newspapers have been responding, however, with increases in their online presences.^[5,17,19,22,23,31,37]

The same story of rapid diffusion is documented for radio and television. Licensed commercial radio began in the early 1900s with the first radio stations being introduced in the 1920s in the United States and Europe.

Today, there are some 12,000 radio stations—commercial and noncommercial in the United States alone. Television broadcasting with a regular schedule was introduced by a station in New York City in 1931. By 1960, roughly 9 of 10 households in the United States owned at least one television, and as of the late 1990s, there were some 219 million television sets in U.S. homes. Riding on these developments was the spread of advertising and public relations as massive enterprises. The first advertising agency as such opened in 1850. U.S. Census figures reported more than 11,000 advertising agencies in the United States and at least half that number of firms specializing in public relations.^[5,17,19,38–40]

The speed of the spread of Internet use is even more startling. The worldwide infrastructure as we know it today first became available for public use in the early 1990s with the development of graphic interfaces and the World Wide Web. Current penetration to the U.S. population is more than 70%; Europe 48%; Oceania/Australia 59%; globally 22% (more than 1.5 billion users).^[41]

The astounding growth and diffusion of all media technologies has had extraordinary impacts on the social fabrics of societies already changing rapidly because of the impacts of the industrial revolution. The growth in the entrepreneurial working class meant, for example, more leisure time for many, leading to clamoring for more diversions to fill that time. The rise of mass production of products and services coupled with the use of advertising and public relations as dissemination tools spread in rapid succession of all manner of changes in the distribution of goods and services, and impacts on lifestyles. Those with more flexible incomes clamored for products. Those with reading literacy reached for newspapers, books, and magazines, and, of course, eventually all media. The projection that some media would disappear during these evolving conditions is only in part true. Particular technologies have disappeared but the differential needs they serve varied audiences remain. If anything, the brunt of evidence suggests complementarities between media technologies rather than competitions.^[18,19,28]

One major phenomena that must be emphasized as characteristic of the growth of mass media is that for first time media did not demand reading literacy as defined by elites. In general, media formerly controlled by and serving elites became mass-based. Citizens worldwide began to get access to pictures of their worlds formerly hidden from their views. They learned, for example, of misdeeds of their own leaders not reported locally; or how ordinary citizens lived in other parts of the world. Some media observers worried about an era of rising expectations that could not be met in a realistic (in one framing of the critique) or brutal (in another) reality. Others foretold how ordinary citizens would seize media for their own purposes as, for example, Bolivian miners' unions did as early as the 1950s. Others were deeply worried about the impact of media, such as film and radio on ordinary

citizens, particularly children. Others were concerned with the need to educate populations with a new kind of literacy—media literacy.^[5,15–17,20–22,31,35,42]

These polarizing concerns between potentially positive and negative communication impacts got entangled in growing arguments about who gets to decide what is positive and what is negative. Lack of consensus mirrors the now documented truism that media developments as envisioned by those controlling media technology rarely turn out as expected. This has been particularly so as the media have evolved from elites communicating with elites, to elites communicating to the masses, to masses communicating with each other, to masses organizing and communicating back at elites.

As we look broadly at historical media developments, the same expectations of communication and its potential impacts in society have been repeated for each successive media development. But the debate is not new. Even in the very early years of rhetoric in ancient Greece, there were discussions on the ethics of using persuasive manipulation. The debate centered on whether these approaches to communicating were necessary as an antidote to ignorance and mob rule, or abuses of power and intrusions upon the sanctity of human consciousnesses.^[5,16]

The Phases of Institutionalization

Most histories of the rise of communication studies have essential agreement on the phases of events. In the very earliest period—prior to the institutionalizing of communication-named units—the teaching of rhetoric was fairly well established. Rhetoric was part of the first curriculum at Harvard in 1636. By the end of the 1700s, it was well established in most of the Ivy League. An emphasis on rhetoric spread throughout the country. However, as more institutions were established, this emphasis slowly evolved to focusing primarily on the practical skills of discussion, speaking, and oratory. Increasingly these courses were usually located in departments focusing on English. By 1910, the academics focused on teaching speech and were large enough in numbers that they founded their own association.

While attention to media studies does not have this long history, the same practice emphasis characterized early developments. As the media were introduced and began to diffuse to mass circulations, it was not long before academic courses focusing on media skills began to appear. The earliest known course in journalism was introduced at the University of Leipzig in 1671. In the United States, in the 1860s, Southern Civil War leader Robert E. Lee introduced journalism training to assist postwar reconstruction at what is now the University of Washington and Lee. The University of Missouri introduced journalism training in 1878. The Wharton School started a business journalism school in the early 1900s.^[5,17,22,23]

The same growth patterns ensued for each media development in turn. The first instruction in advertising was offered at New York University in 1905. Less than 30 years after Edison's invention, cinema studies courses followed in both Europe and the United States by 1920. Courses in radio broadcasting also began to appear in the 1920s and early 1930s. The first master's degree in radio broadcasting was offered in the United States in 1931 at the University of Wisconsin.^[5,17,31]

These early attentions to communication education did not include the term "communication" in their names and almost all focused on practical training. While in general, speech training was located in departments of English and journalism training was either located there or in new separate units, it is really impossible to generalize where these units were placed in academic structures. Until attention to media began to coalesce in a consciousness of media as part of a communication revolution, the spread had a capricious character.^[5]

It was when the mass media exhibited widespread diffusion and potentially negative impacts on society that attentions were directed to studying these impacts in the hopes of understanding and abating them. In the 1930s and 1940s, most of these attentions were manifested in the development of temporary centers, institutes, and programs. Columbia University, for example, established an office of radio research, launched a readability laboratory, and subsequently established a bureau of applied social research which specialized for a period in studying communication problems. Princeton University, with Rockefeller funding, established a center for monitoring short-wave broadcasting during WWII. The Chicago School introduced an interdisciplinary course focusing on communication and propaganda that eventually led to an interdisciplinary center. Ohio State University's Bureau of Educational Research launched the Payne Fund studies on the impacts of film on children with funding from the Motion Picture Research Council.^[5,17,31]

From the 1940s on, new programs, centers, and projects began to emerge at what has been estimated as at least one per year.^[5] Audience research was introduced into already established journalism units, for example, at the University of Minnesota in 1944 and University of Iowa in 1946. Speech focused units began to add social scientists to their faculties and introduce social science focused courses.^[5,16,21]

In the 1940s, units with the communication label began to appear. The first unit to specifically use the communication label was a communication research center at the University of North Carolina, emerging out of speech and theater. The Institute of Communication Research with a media focus was established at the University of Illinois as was the University of Iowa's communication research center, also with a media focus.^[5,17]

By the 1950s, the label communication was popular both in academic and governmental circles as well as

public imagination. The first mention of communication studies as an academic enterprise in *Webster's Dictionary* was in 1951. The first college identified as such was established at Michigan State University in 1955. The first doctorate was awarded under the communication label in 1956. Courses and institutes in higher education that focused on something they specifically called communication increased from the early entrees in the 1950s to explosive developments of the 1960s and 1970s. Most of the early developments occurred at the Big 10 universities of the Midwest. Exceptions to this were the robust communication-labeled units at the University of Pennsylvania, the University of Washington, and Stanford. Later, communication-labeled units diffused virtually everywhere except, notably, in the Ivy League. Despite the fact that Ivy League institutions were among the first to promote communication research initiatives, they have not incorporated communication studies into their formalized curricular hierarchies.^[5,17]

As the growth of communication studies marched on, the various media focused units—journalism, radio, advertising, film, and television—began to change their names to incorporate the "communication" word. Programs merged and coalesced into schools and colleges of mass communication. Likewise, units coming from the speech communication trajectory began to change their names.

The growth statistics on the introduction of departments, schools, and colleges were remarkable. In less than 50 years, by 2006, some 1300 colleges and universities in the United States had communication focused programs or departments. In 2005–2006, according to the Chronicle for Higher Education, 81,661 degrees were awarded in communication at the bachelor's, master's, or doctoral level—about 5.2% of all degrees conferred. This number rose from 14,794 in 1967–1968 (1.8% of all degrees).^[43]

With continued growth, there were challenges. Primary among these were the impacts of academic cutbacks in the 1980s and resulting pressures on the different communication-focused programs for retrenchment. This involved mandates for mergers and elimination of duplications. This also led to many attempts by communication scholars to show internal coherencies in communication studies with its emphasis on communication as fundamental process. These efforts continue today.

Further, communication suffered and continues to do so in many locales from being seen as academically inferior, in many minds tarnished by its legacies in practical training. Some have seen this as a result of academic elitism and erroneous stereotyping of communication studies as merely a field that focuses on practice and not a discipline that focuses on basic research and theory development.^[5] Yet, at the same time, communication skills and understandings have increasingly been documented as among the skills and understandings college educated graduates need.^[4] Further, students continue to seek out

higher education courses in communication, both for media or speech emphases. Popular sentiment has supported this trajectory. One sample indicator of the place of communication in public consciousness is that as of November 11, 2008, there were more than 649 million Google hits to Web pages dated 2008 with the word “communication” in them and more than 140,000 titles dated 2008 with the “communication” word in them in Google scholar.

Structures for Handling the Diversity

Space prevents any attempt to show the numerous ways in which those involved in the study of communication have partitioned and organized their topics of interest. There are some basic large categories of attention most easily discerned by examining texts developed for introductory courses. These are listed in the first paragraph of the section “Two Primary Institutions—Speech and Mass Communication.” However, from textbook to textbook these can markedly disagree, not so much in the specific details but in the ways in which the categories are organized.

For the most part the categories for organizing curricula and attentions in communication studies capture some basic enduring nouns into which the communication terrain has been divided. What is missing are the many ways in which different researchers, academic units, organizations, and journals have parlayed their interests into specialized contexts, cultures, and domains. Looking across category schemes, we find divisions emphasizing, for example: societally important foci of attention (e.g., health, political communication, marriage, peace); communication processes (e.g., sense-making, dialogue, leadership); goals (e.g., persuading, informing, educating); audiences (e.g., women, men, children, parents, minorities). The list goes on.

The diversity shows most clearly by examining Tables 1–3, profiles of the three largest comprehensive organizations that have emerged over the years to support communication studies with annual conferences and journal production. These three organizations, as well as a number of equally robust but more specialized organizations, have grown from relative isolation over a 50-plus year period to their current formations. Each has a distinctive character arising from its own historical lineage. Each has exploded in growth in short periods of time and has robust conferences and supports a roster of journals. Each over the years has converged more and more onto common interests while retaining their distinctions, providing room for the diversities of interests of their members, and simultaneously setting aside a significant portion of attentions to communication in the broadest and most widely applicable sense.^[1,2,5,32–34]

Today, the three most comprehensive organizations that attract members from the United States are, in order of historical emergence: the National Communication

Association (NCA), the International Communication Association (ICA), and the International Association of Media and Communication Research (IAMCR).^[32–34] There are important organizations with more specialized foci that are not being highlighted here. In the U.S. context, examples include the Association for Education in Journalism and Mass Communication, the Broadcast Educators Association, and the American Association for Public Opinion Research. Each has robust membership and conference attendance. Each supports one or more journals. There are as well numerous communication studies associations in virtually every country and region of the world, each exhibiting the same essential core foci on communication as fundamental process and each exhibiting differences arising from their unique historical lineages and current cultural and political-economic interests.^[5,17,22,23]

The importance of focusing only on the three most comprehensive organizations which today attract substantial U.S. membership is to examine them as exemplars of how the structures that support communication studies focus on core interests in communication while simultaneously handling the diversity in contexts, cultures, domains, and environments that are the locales where essential communication processes play out their roles and impacts. Tables 1–3 profile each organization’s history, current membership composition, and current emphases as displayed in subgroup category names and journal titles. It is in these lists that one gets a glimpse of both the core of communication studies and its parts.

In 2008, ICA (Table 2), for example, had a special interest group focusing on game studies, a recent emergence, while at the same time its journals covered a broad spectrum of communication interests. One special interest group in ICA focuses on communication and history, a reflection of how ICA, strongly anchored in emphases on social scientific studies, is admitting more and more humanities based interests into its roster. For NCA (Table 1), one of the most recent divisions to be added focuses on spiritual communication, a reflection of a general societal turn to interests not usually covered by normative studies of how people use media and messages. National Communication Association’s journals also reflect a broad spectrum of interests—both humanistic and scientific—and retain as well the organization’s focal origins on communication education. International Association of Media and Communication Research’s (Table 3) subgroups reflect its historical lineage and cover a number of special foci more likely to be catapulted into membership attentions by the historically international character of the organization. In 2008, working groups were listed, for example, for diaspora and communication, Islam and media, as well as for emerging media foci common to all three organizations—e.g., the digital divide, comic art, and popular culture.

Table 1 Profile of the National Communication Association.

Main organization	Subgroup structures as of 2008
National Communication Association	<i>Divisions</i>
http://www.natcom.org	African American Communication and Culture
Founded 1914	American Studies
<i>Former names</i>	Applied Communication
Speech Communication Association	Argumentation and Forensics
National Association of Academic Teachers of Public Speaking	Communication and Aging
<i>Current mission statement</i>	Communication and the Future
...a scholarly society that works to enhance the research, teaching, and service provided by its members on topics of both intellectual and social significance	Communication and Law
...the oldest and largest national association	Communication Apprehension and Competence
promoting communication scholarship and education	Communication Assessment
...promotes study, criticism, research, teaching, and application of the artistic, humanistic, and scientific principles of communication	Communication Ethics
<i>2008 statistics</i>	Communication and Social Cognition
7700+ members	Communication as Social Construction
<i>Home locations of members</i>	Critical and Cultural Studies
20+ countries, mostly United States	Environmental Communication
<i>Conference attendance</i>	Ethnography Division
4000+ attendees at typical annual conference	Experiential Learning in Communication
an estimated 4000+ presentations	Family Communication
in 1000+ programs	Feminist and Women's Studies
<i>Conference sites</i>	Freedom of Expression
2008, San Diego	Gay, Lesbian, Bisexual, Transgender and Queer Communication
2007, Chicago	Group Communication
2006, San Antonio	Health Communication
2005, Boston	Human Communication and Technology
2004, Chicago	Instructional Development
*4 regional U.S. associations—eastern, southern, western, central, sponsor own annual meetings and journals	International and Intercultural Communication
<i>Journals available to members</i>	Interpersonal Communication
Communication & Critical/Cultural Studies	Language and Social Interaction
Communication Education	Latino/Latina Communication Studies
Communication Monographs	Mass Communication
Communication Teacher	Nonverbal
Critical Studies in Media Communication	Organizational Communication
Journal of Applied Communication	Peace and Conflict
Journal of International & Intercultural Communication	Performance Studies
Quarterly Journal of Speech	Political Communication
The Review of Communication	Public Address
Text & Performance Quarterly	Public Relations
	Rhetorical and Communication Theory
	Semiotics and Communication
	Spiritual Communication
	Theater
	Training and Development
	Visual Communication
	<i>Sections</i>
	Communication Centers
	Community College
	Elementary and Secondary Education
	Emeritus/Retired Members
	Master's Education
	Student
	Undergraduate College and University

In each of these organizations, the subgroups and journals represent the presence of discourse communities substantial enough in size that they have parlayed for themselves a share of convention and journal resources. Each is, as well, a trace of the many different topics and

emphases brought to bear on teaching and research foci. Throughout academic units focusing on communication studies in the United States and throughout the world, the same play between the past and the present, the center and the peripheries can be observed.

Table 2 Profile of the International Communication Association

Main organization	Subgroup structures as of 2008
International Communication Association http://www.icahdq.org	<i>Divisions</i>
Founded 1950	Communication and Technology
<i>Former names</i>	Communication, Law, and Policy
National Society for the Study of Communication	Ethnicity and Race in Communication
<i>Mission statement</i>	Feminist Scholarship
...aims to advance the scholarly study of human communication by encouraging and facilitating excellence in academic research worldwide. The purposes of the Association are: (1) to provide an international forum to enable the development, conduct, and critical evaluation of communication research; (2) to sustain a program of high quality scholarly publication and knowledge exchange; (3) to facilitate inclusiveness and debate among scholars from diverse national and cultural backgrounds and from multidisciplinary perspectives on communication-related issues; and (4) to promote a wider public interest in, and visibility of, the theories, methods, findings and applications generated by research in communication and allied fields.	Global Communication and Social Change

<i>Journals available to members</i>	Children, Adolescents and the Media
Communication Theory	Communication and History
Communication, Culture ... Critique	Game Studies
Journal of Computer-Mediated Communication	Gay, Lesbian, Bisexual and Transgender Studies
Human Communication Research	Intergroup Communication
Journal of Communication	

In essence, across the many diversities can be found a core concern for researching, theory building, and applying through practice understandings of communication as a fundamental and universal process by which humans somehow transmit, exchange, or share meanings. While, for example, in the big three organizations each subgroup may have its own emphasis, the boundaries between them

have not been impermeable. Subgroups within and between the organizations regularly come together in journals and conventions to intermingle and produce collaborative work that recognizes core interests in communication. As a bottom line, it is fair to describe communication studies as an academic force that has continuously encouraged unity amid its essential diversity.

Communication Studies and Its Productive Tensions

Communication studies as a terrain of academic focus was welcomed into the academy on the tail of the explosive

spread of mass media and the interest, particularly by government and policy makers, to apply the tools of social sciences to studying, understanding, and curbing negative effects from the media as well as promoting positive ones. Yet, from the beginning the forces that put the

“communication” word on the map harbored contradictions within them.

These contradictions are many. In terms of historical lineages, communication studies attached itself to two established teaching missions: one focused on training media practitioners; the other focused on training citizens and leaders for oratory and discussion in public forums. This introduced immediate contradictions between practice and scholarship, one that remains today. As science was emphasized more and more as an appropriate form for study, the humanities way of knowing the world collided with the scientific way.

These two historical polarizations in many ways were simply surface symptoms of a host of other contradictions that have beset communication studies. Those studying communication disagree about: how to know the world, what to do with the knowledge, how to handle differences, and what to call deviance and what not; whether the role of leadership is to control, correct, and persuade, or facilitate and engender opportunity; how best to understand others and even whether the understanding is worth the effort; whether communication and, in particular, media damages us and our societies, or helps; whether communication is something that might be used to make the world a better place; whether this very idea can be considered ethical or impositional.^[5,10–15]

These tensions and many more can be seen galloping through discourses in more traditional fields of study, both in the humanities and the social sciences. They can also be seen galloping through media news reports on our TV screens and in our newspapers.^[28,34] Yet, it can be argued that communication studies is more impacted because these tensions, if resolvable, must be resolved in communication.^[8,28] Add to this the fact that increasingly our lives are structured and patterned within landscapes of electronic communication that now seem to be making the old distinctions between mediated versus non-mediated irrelevant. These converging forces put communication studies in the center of a hurricane. The subjects of communication studies are what make the hurricane whirl. But, communication studies, like all other centers of academic attention, is whirling along as well.

Both insiders and outsiders look at communication studies and what appears to be a chaotic jumble of incoherent interests and emphases and ask: How can this be a discipline or it is merely a field? Is this even a field, or merely a meeting place? Is this a specialty requiring a discipline or a phenomenon that is now everyone’s business? Debates on these issues continue and are expected to do so for some time.

Yet, despite these disagreements, an examination of communication studies shows that it keeps trying to hold onto the vision of many of its founding fathers—that there is a communicative way of looking at the world and that worldview provides special strengths. Some see this

strength as growing out of communication studies as the practical discipline where one studies how humans use communication to make and unmake and remake their worlds. Others see this as a distinction between the nouns that are the specialized foci of most of the social sciences and humanities, and the verbs of communicating that forge the linkages between peoples across time and space. Some see communication studies’ continuing efforts to retain this core and vision as its special strength and potential greatest contribution. In this sense, the contradictions and chaos that seem to give communication studies an incoherent face can be seen as symptom and cause of both its centralities and its dispersions, its weaknesses and its strengths.

CONCLUSION

The goal of this entry has been to describe the historical emergence and current states of attentions to communication as a phenomenon of academic study; and, to describe the various academic formations today nested under the term communication studies. Because communication studies has been a presence in the academy for less than 60 years, and because it has evolved in the midst of an exploding and rapidly changing communication environment, there are necessarily multiple and competing stories to be told. This entry has attempted to focus both on convergences and divergences across these stories. The entry has reviewed in turn: different meanings for the word “communication” and how and when the term came into popular usage; the two primary historical lineages out of which communication studies has emerged—speech and mass communication; the forces leading to institutionalization and the exploding emergence of the media. The entry has examined the phases in which communication studies became institutionalized and how it has handled its diversity with supporting structures of organizations and journals. The entry concluded with a discussion of how communication studies necessarily holds within its core a series of contradiction that are in essence both symptom and cause of its centralities and its dispersions, strengths, and weaknesses.

ACKNOWLEDGMENTS

The authors wish to acknowledge the extraordinary help provided by the most recent attempts of Arcenas,^[5] Craig and Carlone^[20] to address communication studies and its lineages comprehensively and evenhandedly. The Arcenas dissertation was, in particular, invaluable. The authors also thank Jordan D. Bennett, undergraduate research assistant at Ohio State University for his help with library research.

Communication Policy: United States

D. Linda Garcia

Communication Culture and Technology, Georgetown University, Washington, District of Columbia, U.S.A.

Abstract

This piece examines the impact that competition will have in determining communication policies and goals. It makes the case that, in a regulated environment in which communication technologies were regulated according to a different basis—common carriage, first amendment rights, and public interest standards—it was possible to meet a variety of communication goals. Each technology fostered a different goal. Given convergence, and the deregulation of the communication policy environment, such flexibility is no longer viable. One approach serves all. The result has been that, more than ever before, policy goals must be traded off, one against the other.

INTRODUCTION

The U.S. communication regime reflects the pattern of economic relationships that exist among and between key players as well as the public policy goals and corresponding rules that govern them. For years, the goals and rules of the system and the balance among interested parties were generally accepted and relatively stable. Typically, industry leaders have been the driving forces in developing and promoting communication technologies, competing among themselves for primacy. At certain periods, however, the government has intervened, crafting a new set of communication policies to bring private sector players more in line with public sector needs.

Today the existing set of arrangements is once again being called into question, as technological and socioeconomic developments give rise to new possibilities, new players, and new types of problems. In particular, deregulatory communication policies have shifted more decisions to the market at the same time that technological advances have generated new opportunities in all realms of life. Some applaud these developments, seeing in them new possibilities for innovation and growth. Others fear that if decisions about new technologies are made solely in the marketplace, important social, cultural, and political opportunities might be lost. The contest will continue to be played out in Congress and the courts over issues ranging from telecommunications reform to those having to do with intellectual property rights, privacy, and networking security.

Information-based networks will serve to coordinate economic and political activities in a knowledge-based global economy. The market choices, institutions, and policies that govern them will determine not only the nature of society and the performance of the economy, but also how wealth and power are distributed. For a discussion of the role of institutions in determining economic outcomes, see North.^[1]

Whatever the institutional choices made, they will have far-reaching consequences, for in an increasingly networked society, what is at stake in crafting communication policy is the system of property rights itself. The outcome is not predetermined, nor will it necessarily be efficient. Instead, these new institutional arrangements will evolve over time in response to pressures from economic and political actors who want to restructure the rules of the game in their favor.^[2] Policy outcomes will also be irreversible, at least in the short and medium terms, for once a decision is made, technology tends to become firmly fixed on a given trajectory. This pattern is especially evident with networked information technologies, which require vast amounts of capital and social investment.

Periods of rapid technological advances such as we are witnessing today therefore provide a rare opportunity to reassess the nature of communication policy goals and the mechanisms designed to achieve them. With this opportunity in mind, this entry examines the extent to which today's deregulatory, competitive policy can be expected to meet the wide range of goals that have traditionally been associated with U.S. communication policy and/or new goals that might be required in an increasingly networked environment. First, it lays out the challenges entailed in establishing communication policy goals. Second, it examines the historical goals that have driven U.S. communication policy to date. Next, the entry considers the technological advances and associated social and economic changes that have led to efforts to restructure the telecommunications infrastructure along more competitive lines. Finally, it considers the goals that will be favored in a more market-oriented environment and identifies some new tensions among goals that are likely to emerge as a result.

The entry contends that communication policy based on a strategy of competition alone will not suffice in a networked information society. Given the enhanced role

of communication and information in all realms of life, even greater trade-offs among policy goals are likely. Far from reconciling competing communication goals, the shift in decision making from the political arena to the marketplace will serve to obscure these trade-offs, leading to the emergence of new and perhaps more thorny issues over the long run. To resolve these issues, the government must play a delicate balancing act, employing as it has so successfully done in the past a variety of roles and policy mechanisms.

CRAFTING COMMUNICATION POLICY

Goal setting provides a unique opportunity for policy makers to change course in response to technological advances and changing social and economic circumstances. Rarely, however, do politicians seize such an opportunity, given the dangers and difficulties involved. More often than not, policy goals are instead established and implemented in the context and course of “politics as usual.” When goal setting does take place formally, it usually occurs within the context of major organizational and structural changes.

In the case of communication policy, the effects are likely to be especially far-reaching, because communication is the basis for all interactions and one of the means for organizing society. Given the central role of communications, policy making in this area is generally coupled to other important policy areas. Thus, for example, political concerns about freedom of speech and the free flow of information may easily come into conflict with defense-related concerns, as has recently happened with respect to encryption policy. Similarly, in cases involving pornography or violent media content, concerns about cultural norms and values must be balanced against First Amendment rights.

In crafting communication policy, decision makers must also be sensitive to the importance of three interrelated sectors of the economy—transportation, communications, and information. Mirroring the role of communications in society, these industries are significant, and not just because of their contribution to trade and gross national product. Communication- and information-based goods and services are both intermediary goods and end products, so the impact of policies that affect their costs, availability, and use reverberate across all industry sectors as well as throughout the economy as a whole.

Consideration needs to be given not only to the impact of policy on these key industry sectors, but also on the competitive relationships among communication- and information-related industries. When industry players are able to translate their economic power into political leverage, as is often the case, the problem of sorting out these relationships is greatly compounded. Because political leverage is often distributed unevenly, some industry players

are likely to be favored over others, with little regard for broader public policy goals.

Technology also complicates matters greatly. Because communication is both dependent on as well as mediated by a technology-based infrastructure, decision makers have to craft communication policies with technologies and their distinct characteristics and capabilities in mind. Technologies, however, are very difficult to fathom. Not only are technologies highly complex; they are constantly changing. Crafting sound communication policies therefore requires considerable vision as well as technical expertise.

Even when communication policies are well designed to take technologies into account, they are highly subject to unintended consequences and events. Technology advances, for example, can easily undermine the assumptions on which policy is based. One need only consider, for instance, what can happen to policies designed to affect market structure. Technology advances can alter the rules of the game by affecting economies of scale and scope, the availability of product substitutes, and the costs of production. By providing new opportunities and challenging conventional ways of thinking, technology advances place new demands on the system, creating the need to reassess and reconsider basic communication-related goals.

The U.S. experience in setting communication policy goals reflects the magnitude of the challenges involved. Legislative mandates laying out specific goals have been rare. Once the major guidelines have been established, U.S. communication policy strategies have been derived incrementally over time through a process of administrative and judicial interpretation. This incremental approach only succeeded, however, as long as social and economic conditions were relatively stable and there was a broad consensus on related goals. As described below, in periods of major crisis or upheaval, such as the shift from an agrarian to an industrial society or from a peacetime to a wartime economy, new sets of rules designed to solve new challenges and accommodate new players became imperative.

COMMUNICATION GOALS: AN HISTORICAL PERSPECTIVE

Examining the U.S. communication policy regime from an historical perspective, a number of major communication policy goals can be identified. Established in the context of major social and economic changes—oftentimes brought about by technological advances—these goals were broadly conceived. Recognizing the link between communication and the social and economic orders, policy makers viewed communication as a means and not just as an end in and of itself. In pursuit of these goals, the government adopted a variety of roles and a broad range of policy mechanisms

Table 1 Goals, roles, and policy mechanisms.

Goals	Government Roles				
	Broker	Regulator	Educator	Promoter	Market maker
Achieving democracy	Newspaper exchange	First Amendment		Postal roads; mail subsidies	Intellectual property
National integration	Public school movement	Rate regulator	Extension service; libraries	RFD; land grants; Express Mail	
Efficient interconnection	REA	Common carriage rate regulator		Rate averaging	Antitrust legislation
Cultural concerns	Voluntary constraints	Spectrum licensing must-carry	Educational TV	Public Broadcasting	Ownership rules
Defense and security	Standards industry broker	Censorship; wiretapping		R&D; roads; ARPANET	Procurement policies

that were designed not only to take advantage of new technologies, but also to serve the needs as they were perceived by both key stakeholders and the nation as a whole. These goals, government roles, and policy mechanisms are depicted in Table 1, and they are briefly described and discussed below.

Securing Democracy by Promoting Information Access

Some of the most far-reaching and enduring communication policy goals were established at the time of the nation's birth in the context of a political revolution and a total revision of governmental affairs. These goals reflected the Founding Fathers' preoccupation with establishing a democracy and the importance they attributed to communication and information in securing it.

Occurring at the height of the Enlightenment, the American Revolution was a battleground of ideas. The dissemination of these ideas, and the revolutionary fervor accompanying them, was linked to print technology and the emergence of new channels of communication, such as the religious and merchant networks associated with the growth of discursive literacy. In nineteenth century England, for example, not only did the number of newspapers and periodicals grow by a factor of 10; equally important, journals were distributed more widely—beyond cities to small towns and villages in which a single copy might be read and discussed by a number of persons.^[3]

In the U.S. colonies, for example, newspapers and pamphlets served as the primary vehicle for public protest and revolt, providing a network of political communication that was crucial to revolutionary activities. Thus it was that with the onset of the revolution, printers—functioning as editors and publishers—generated and controlled the flow of public information. In fact, it was in their shops that many political accounts and ideas were exchanged, and although they had strongly opposed British control of the press, they were equally prepared—during the Revolution—to suppress dissenting opinions.^[4,5]

No one appreciated the power of the pen more fully than the Founding Fathers—the architects and ideologists

of the revolution. Fearful of misinterpretation, they excluded journalists from the Constitutional Convention. Seeking to build support for the Constitution, Alexander Hamilton and James Madison disguised themselves as the columnist Publius, and wrote *The Federalist Papers*, a series of newspaper articles, on its behalf. In the new nation, however, in which competing interests were institutionalized and balanced against one another, open communication was to be the rule.

Distrusting government as much as they valued information, the Founding Fathers looked to the federal government to play a minimalist role. To promote the free and independent flow of communication, they relied for the most part on prohibitions against government interference in content, as well as on subsidies and targeted economic incentives. At the same time, however, the government was authorized to use its postal authority to promote information. For these purposes, the Founding Fathers incorporated three clauses into the Constitution. These provisions guaranteed freedom of speech, assembly, and the press, and authorized the federal government to protect intellectual property and to establish a system of postal roads. Designed with print technologies in mind, this approach provided adequate for an agrarian society, in which people who had dealings with one another were in close proximity and the costs of producing and distributing information were well within individual reach.

The first amendment

The First Amendment to the Constitution, covering freedom of speech, religion, assembly, petition, and the press, forbade Congress from any actions abridging those freedoms. The amendment gave American newspapers a degree of liberty unknown elsewhere. Applied most fully to print media, it has consistently meant private ownership, freedom from prior restraints, virtually no content controls, and relatively limited liability for the consequences of a message. Except during times of war and social stress, this value included the right to criticize government vigorously. Viewed as a centerpiece of American government, major cases involving its applicability did

not arise until after World War I with the introduction of the “clear and present danger” standard. Subsequent Court interpretations have ranged from a strict absolutist view, which interprets the First Amendment literally, to a more restrictive view, which allows for exceptions in cases such as obscenity, libel, and national security. The Court has generally adopted an intermediary stance between these two positions; however, while consistently holding that freedom of speech is not absolute, it has defined exceptions very narrowly.

The protection of intellectual property

Article 1, section 8 of the Constitution authorizes the federal government to grant intellectual property protection. Its express purpose was “To Promote the progress of the Exclusive Right to their respective Writings and Discoveries.” Generally speaking, there are four different forms of intellectual property protection—copyright, patents, trademarks, and trade secrets—each with its own set of rights and obligations. Of these, the copyright regime is the one that has until recently been most closely associated with communications policy.

Like the free flow of information, the promotion of sciences and the useful arts was closely linked to democracy; a democratic polity was viewed as a prerequisite for advancement in applied science, while technological achievements were expected to provide the physical means of achieving the democratic objectives of political, social, and economic equality.^[6,7] To assure that intellectual property protection would play this dual role, the Founding Fathers made it a statutory right granted not as a reward per se but rather as an incentive to achieve a specific public policy goal. James Madison—the principal author of the intellectual property clause—was aware of the monopolistic connotations of such a governmentally granted, exclusive right. He distinguished the American system of intellectual property rights from previous ones that he believed were more pernicious. To avoid the evil of monopoly, Madison intended that the exclusive right afforded by copyright be narrowly circumscribed; owned by “many” and “granted for only” limited period of time (p. 84).^[7]

Although the rights granted under the first Copyright Act of 1790 corresponded to the capabilities of the printing press, the law has been extended over time to incorporate new technologies.

Establishing postal roads

Like its constitutional counterparts, Article 1, section 8, paragraph 7, which authorizes Congress to establish a system of postal roads, was intended to assure that all citizens in the burgeoning democracy had access to a broad range of information. The writers of the Constitution were acutely aware that building a nation would

require a national communication infrastructure, and the development and evolution of the postal system was designed to serve this end. Setting aside factional differences, Federalists and Republicans rallied behind a postal policy to encourage newspaper circulation. Favoring the exchange of political and business information over interpersonal transactions, Congress set postal rates several times higher for letters than for newspapers. The distribution of news was also encouraged through postage-free exchanges among newspaper editors. In 1936, the Post Office also inaugurated postal express services to speed the flow of market information.^[8]

PROMOTING NATIONAL INTEGRATION BY SUPPORTING MASS MEDIA AND EDUCATION

The situation facing policy makers in the post-Civil War period was radically different from that which had confronted the Founding Fathers a century before. No longer unified around a set of revolutionary goals, the nation was coming apart at the seams. Pressing problems included the reconciliation of the North and South, the integration of the western territories, urbanization, the absorption of new immigrants, and the shift from agriculture to industrialization.

Like the Founding Fathers, post-Civil War decision makers turned to communications policies for answers. Instead of focusing on ways for people to exercise their individual differences and choices, however, they began to view communication from a more organic perspective—as a means of socializing individuals and integrating them into specialized roles within a larger community. Such a radical change in approach is understandable, given the prevailing intellectual and political thinking of the day. Support came from the Progressive movement as well as from the burgeoning field of sociology, which stressed the role of communication.^[9] These groups looked to the media not only to enhance public understanding but also to improve society. As the philosopher John Dewey described, “The duty of the present is the socializing of intelligence—the realizing of its bearing upon the social practice.”^[10]

Support for the mass media

In keeping with this perspective, in the late 1800s the federal government extended its postal subsidies to the newly emerging mass media. Taking advantage of technology advance and advertiser financing, publishers launched a new media genre—low-cost magazines that were geared to a mass, middle-class audience. Magazines such as *The Saturday Evening Post* and *The Ladies' Home Journal* provided a mechanism, by which mass retailers—advertising brand name consumer goods—could reach out to the public.^[11]

Given the country's expansion westward, the mass media were considered essential to the development of a national market. Moreover, because the mass media could breach the social and economic cleavages that beset the nation, many hoped it would foster a sense of national identity as well as the peaceful resolution of differences.^[12] Members of the influential Progressive Movement were especially hopeful in this regard. To assure widespread access to magazines, the government—in 1890—inaugurated the Rural Free Delivery (RFD) Program. The targets of the RFD subsidies were the underserved, remote, high-cost rural areas. Although costly, rural free delivery helped to improve access. Over the next four decades, the distribution of periodicals increased 20 times faster than the population at large.^[13]

The public school movement

Nowhere was the new communication philosophy embraced more enthusiastically than in the realm of public education. Whereas in the early years of the republic education was regarded as a private affair—provided for the benefit of the well-to-do and the professional classes—in the post-Civil War era it was considered a matter of national survival.^[14] Looking to education to unite the nation and preserve its social and economic integrity, politicians and educators joined together in a public school crusade. By educating American youth in public schools, they hoped to inculcate a common set of patriotic, Protestant, and republican values.^[15,16] Moreover, they believed such schools would socialize the growing number of people from so many different backgrounds for increasingly differentiated economic roles.

To perform this function, public schools were structured in accordance with business principles. Vocational education and guidance were introduced as part of the educational curriculum. Assuming that the majority of Americans would be working at industrial jobs, educators believed that vocational education would serve not only the best interests of individuals, but also society.^[17,18]

Public libraries were likewise targeted for support. In rural areas, book deposit stations were set up in grange halls, neighborhood stores, fire stations, and women's clubs. In cities, libraries and adult education programs were set up to provide a haven for working class immigrants.^[19]

Agricultural extension

In its educational efforts, the government also reached out to farmers, who bore much of the brunt of the socioeconomic changes taking place. Describing this situation, Wayne Rasmussen notes,

The revolution generated by the Civil War catapulted the nation's farmers not only into a world of complex social and economic forces that were too volatile and powerful

for individual farmers to confront by themselves. It seemed that the appearance of more complex and productive tools intended to guarantee the farmer's survival had made that survival more complex.^[20]

To help them adjust to changes in the economy, the government began to develop and transfer modern technology to agriculture. It thus initiated the Agricultural Extension Service in 1914. As provided under the Smith-Lever Act, the U.S. Department of Agriculture and the land grant agricultural colleges were charged with establishing partnerships between university extension and experiment stations, and between country extension agencies and country farm bureaus. Within a few decades, an elaborate network of public and private partners had achieved its goal of farm modernization.^[20]

Land grant colleges and industrial education

Universities were also overhauled to keep pace with social and economic changes. The land grant colleges, provided for under the Morrill Act of 1762, played a critical role in this regard. Under this law, land was provided to the states, the proceeds of which were to be used to teach agronomy and mechanical arts. Subsequent legislation provided federal support for research and the operation of land-grant colleges. Designed to meet the role of an industrial economy, these universities were called on to expand beyond the traditional role of training gentlemen as preachers, lawyers, and doctors. Democratic and populist in origin, they were open to children of all backgrounds. Moreover, unlike traditional colleges, they were not isolated in their communities. Through their agricultural experiment stations and their service bureaus, their activities were designed to foster economic development in the states.^[21]

The impact of the Morrill Act was clearly evident in the field of engineering. Before its passage, state legislatures had been reluctant to invest in technical education. By 1886, there were 110 schools of engineering.^[22]

Promoting Universal Efficient Interconnection via Regulation

To meet the needs of a rapidly expanding and increasingly complex industrial economy, large-scale, integrated networks, as well as a more activist federal policy, were called for. Although new technologies—such as the railroads, the telegraph, and the telephone—emerged to accommodate the needs of an industrial economy, acting on its own, the market could neither generate the financing nor promote the economic coordination necessary for their ubiquitous deployment and diffusion.

The public was also much less inclined to provide unquestioned support for business. Middle class reformers describing themselves as “progressives” opposed the

concentration of economic power. They called on government to control corporate abuses and reduce the negative impacts of rapid industrialization and urbanization. Farmers and others living in the West accused big business, especially the oil companies and railroads, of price gouging. In addition, labor—emerging as a movement in its own right—became increasingly critical of business.

This decline in the support of business reflected the economic uncertainty of the time. The exceptional growth that had characterized the period from the end of the Civil War to the turn of the century was accompanied by fierce competition. Growth in economic activity gave rise to overproduction, which led in turn to three severe economic downturns (from 1873 to 1877, 1885 to 1887, and 1893 to 1897). In this economic climate, the rate of business failure was exceedingly high. To survive, businesses employed whatever measures they could, including cartels and other pooling arrangements, predatory pricing, or direct control through horizontal mergers.^[23]

Seeking a more stable economic environment, business and political reformers alike called for a new transportation and communication policy regime. In developing a new strategy, the federal government drew on the concept of a public service company, which in England dated back to the fourteenth century.^[24] As the term was applied in the United States, public service companies were those whose products or services were considered essential to a community's well-being and way of life. Given their importance, these companies were required to provide services to everyone on a nondiscriminatory basis, while government was called on to assure compliance.

United States policy makers adopted this model for regulating the rapidly growing and increasingly powerful transportation and communication industries, which fit neatly into its framework. Embedded first in the Interstate Commerce Act of 1887 and later in the Communications Act of 1934, this regulatory solution allowed businesses to operate in the private sector while providing some social control over the single-mindedness of the market. Facilitating inter- and intraindustry coordination—even, when necessary, at the expense of monopoly—it promoted network interoperability, economic viability, and universal service at the time in which the communication infrastructure was becoming ever more important to the American way of life.

The railroads and the interstate commerce commission

Because of its high fixed costs, fluctuating demand, scale of operations, and need for coordination and specialized engineering skills, the railroad industry was from its inception prone to exceptionally high transaction costs. After numerous failed efforts by companies to jointly develop standards, coordinate operations, stabilize prices, and rationalize the industry, railroad industry magnates

began to merge their operations, frenetically buying up their customers and competitors. In their efforts to establish greater market stability, the railroad companies alternated their strategies between two extremes—cutthroat competition or pooling and price fixing. Because the economic stakes and uncertainties were so high, neither strategy proved successful. Cutthroat competition was ruinous for all, but cooperative agreements were untenable without some mechanism for enforcement.^[25]

Railroad companies' competitive machinations quickly spilled over into the political arena, giving rise to demands for reform. Most vocal in calling for reform were small business owners and farmers in the West who had been forced by the railroad companies to subsidize the discounted rates offered to the large eastern industrialists. An increasingly disgruntled and activist labor force soon joined these voices.

Under mounting pressure, the government established the Interstate Commerce Commission in 1887 to regulate the railroads to assure just and reasonable rates.

Regulating the telegraph

Requiring large-scale technologies and national interconnection, the telegraph—like the railroads—posed questions about the industry's structure and its relationship to government. Although the federal government had provided \$30,000 for the construction of the first telegraph lines in the United States, it was reluctant to play a more active role. The post office, already burdened by deficits, was disinclined to assume responsibility for the Washington D.C./Baltimore line, which appeared to have only limited commercial value.

Absent government involvement, telegraph firms strung wires between towns of any commercial consequence. With dozens of companies competing, however, customers were wont to secure rapid, reliable transmission. Under these circumstances, businesses preferred dealing with a few reliable national firms. Happy to oblige, Western Union absorbed its competitors, obtaining a near monopoly.^[26] Concerned lest a single national telegraph abuse its power, the government opted once again for a common carrier system. In 1866, Congress granted monopoly privileges to Western Union in return for its promise to provide "services like a common carrier, namely to all comers without discrimination." In 1893, the U.S. Supreme Court ratified the telegraph's status as a common carrier, and Congress legislated it in the Communications Act of 1934.

Regulating the telephone

The history of the telephone industry followed a similar pattern. By 1902, 451 out of 1,200 cities had two or more phone companies. As with the telegraph, business users found competition burdensome. At the same time, cities and states increasingly expected telephone providers to

operate for the public's convenience. Responding to a serious movement for government ownership, AT&T mounted a public campaign, arguing that telephony was a natural monopoly and regulation was the only way to reduce "wasteful competition" and assure universal service. As Theodore Vail, AT&T's chief operating officer, described his vision of the telephone industry in the annual report of 1910,

The position of the Bell system is well known.... The telephone system should be universal, interdependent, and interconnected, affording opportunity for any other subscriber of any other exchange...annihilating time or distance by use of electrical transmission.

Congress was amenable. It gave the Interstate Commerce Commission regulatory authority over the Bell system in 1910 and shifted jurisdiction to the Federal Communications Commission (FCC) in 1934 with the passage of the Communications Act.

Managing Cultural Concerns

Electronically based media presented government with a novel dilemma, which threatened to pit public concerns about media impacts against the constitutional guarantee of First Amendment rights. Early in American history, political thinkers and policy makers had looked to the newspapers to enlighten and empower the public. With the advent of popular electronic media such as film and broadcasting, however, concerns about cultural values and negative impacts came to the fore.

Electronic media were considered different in a number of respects. Capable of reaching a mass audience on a simultaneous basis, film, radio, and television broadcasting appeared inordinately influential. At the same time, their commercial nature and dependence on advertising raised concerns lest these media demean culture and stifle political discussion by appealing to humanity's lowest common denominator. Because these media transmitted content directly into the home, listeners and viewers seemed powerless in defending against unsolicited messages.

As Secretary of Commerce Herbert Hoover described the situation with respect to radio:

Radio has passed from the field of an adventure to that of a public utility. Nor among the utilities is there one whose activities may yet come more closely to the life of each and every one of our citizens, nor which holds out greater possibilities of future influence, nor which is of more potential public concern. Here is an agency that has reached deep into family life. We can protect the home by preventing the entry of printed matter destructive to its ideals but we must double guard the radio.^[27]

The fear that mass media would unduly influence the public was fueled by their use of propaganda during the

Second World War. Although propaganda had proved critical to the military effort, it appeared more sinister in the postwar period. People were concerned lest the media's manipulative techniques be used against them. In fact, in his best-selling book *The Hidden Persuaders*, Vance Packard had accused advertisers of cynically using propaganda to manipulate American consumers.^[28]

Postwar scholars and social critics reinforced these worries. Bemoaning the public's reaction to the media's "pseudo-environments," Walter Lippman called for the replacement of journalists by social scientists who, he claimed, would organize and interpret events more objectively.^[29] At the same time, social psychologists—such as David Riesman in his book *The Lonely Crowd*—began to link the mass media and mass opinion to negative social and political outcomes.^[9]

In addressing these concerns about content, the government was limited by the First Amendment. By leveraging its ownership of the public airways and allocating them according to "public interest criteria," however, the government was able to pursue a number of content-related policy goals within the bounds of the Constitution.

Voluntary censorship

Voluntary private censorship was the preferred means of influencing media content. With voluntary censorship, not only could the government achieve its public interest goals; industrywide standards also allowed media providers to appease the public without being competitively disadvantaged. Responding to its critics and the threat of government intervention, the motion picture industry was the first media provider to set voluntary content standards through the National Board of Censorship of Motion Pictures. Movie critics were concerned lest films lead to the vulgarization of daily life. As Michael M. Davis of the Russell Sage Foundation argued in 1912, "recreation within the modern city has become a matter of public concern; laissez faire, in recreation as in industry, can no longer be the policy of the state." Responding, local governments began to employ ordinances, such as those pertaining to Sunday blue laws, safety, and community morals, to censor content and when deemed necessary to shut theaters down (p. 44).^[9]

When faced with the prospect of regulation, broadcasters followed suit. Thus, as soon as the Federal Radio Commission made its intention known to scrutinize broadcast content in allocating renewal license, the National Association of Broadcasters (NAB) wasted no time in developing an industry code of standards. Similarly, the first NAB television code was adopted in 1951 shortly after Senator William Benton threatened to establish a national citizen's advisory board that would oversee programming and submit an annual report to Congress assessing the extent to which broadcasting served the public interest.^[30]

Although voluntary in nature private sector content standards have proved problematic. Indeed, over the years broadcasters have often been chastised for “self-censorship.” Critics claim that because broadcasters must appeal to a broad advertising base, they avoid controversy by diluting their programming. Voluntary content standards have also been challenged on both antitrust and First Amendment grounds. In 1979, for example, the court—in *Writers Guild of America, West, v. ABC*—questioned whether the government had unduly pressed the NAB to voluntarily agree to a one-hour evening segment of programming for “family viewing.” When the Justice Department challenged the code on antitrust grounds, the NAB abandoned its standards altogether.^[31]

Spectrum licensing

When voluntary standards have not sufficed, the government has leveraged its ownership of the public airwaves to force broadcasters to operate stations in accordance with “the public interest, convenience, and necessity,” as provided for in the Communications Act of 1934. Such a proactive regulatory structure was considered justified, given the chaotic situation in the early days of broadcasting and the industry’s reliance on a limited public spectrum. Policy makers and industry representatives alike believed that without some means of allocating the public spectrum the airwaves would become so overcrowded and interference so rife broadcasting would be precluded. Thus it was, for example, that broadcasters aligned in 1922 to form the NAB, with the express purpose of promoting radio regulation. Commenting on the public mood of the time, Secretary of Commerce Herbert Hoover described the situation as “one of the few instances that I know of when the whole country is earnestly praying for more regulation.”^[32]

Accordingly, broadcasters have been required to provide among other things local content, news and public affairs programming (with adequate and unbiased coverage given to controversial issues), and educational fare for children, as well as equal time for the use of stations by political candidates. While restraining the FCC from actions considered excessive, the courts have generally sanctioned the broadcast regulatory regime on the grounds that spectrum—being scarce—needed to be rationed.

Setting the tone for the future in the landmark case *Red Lion Broadcasting Co. v. FCC*, the Supreme Court considered the constitutionality of the Fairness Doctrine:

Broadcast frequencies constitute a scarce resource whose use could be regulated and rationalized only by Government. Without Government control, the medium would be of little use because of the cacophony of competing voices, none of which could be clearly and predictably heard. [Thus] Every licensee who is fortunate in obtaining

a license is assumed to operate in the public interest and has assumed the obligation of presenting important public questions fairly and without bias.^[48]

Must carry rules

The availability of spectrum was not an issue, however, when the FCC issued the *Cable Television Report and Order* in 1972, laying out comprehensive rules for the cable industry. In the late 1960s, small cable operators were joined by larger systems that aimed to greatly expand their markets. In response, broadcasters pressured Congress to restrict cable. The FCC reluctantly issued a series of rulings that had the cumulative effect of restricting cable development.

Under the *Cable Television Report and Order* in 1972, cable systems were freed to expand to the top 100 markets, but as a quid pro quo they were subject to “must carry rules” requiring operators to provide channels for educational institutions, municipal governments, and public access. Moreover, to assure the viability of free television and the availability of community programming, cable operators had to carry local broadcasting companies’ signals.

Cable posed a potential threat to the FCC’s vision of a localized television system, because if cable operators began to import distant signals into local markets, they might drive local stations out of business. This danger only became apparent as cable began to grow and expand into major markets.

Public broadcasting

Although public interest regulation helped to limit some of the negative aspects of broadcasting, it did little to foster high-quality content. For such purposes, a more direct and concerted effort was required. In the United States, in which government ownership of the media was not an option, a hybrid system of public broadcasting was devised. To preserve the system’s integrity, Congress devised a decentralized structure, which placed the individual stations at its center.^[34] In addition, it set up the Corporation for Public Broadcasting (CPB) with the dual purpose of developing a nationwide broadcasting system and acting as a buffer between broadcasters and government. The corporation itself was prohibited from owning and operating any broadcast or cable organization, interconnection system or facility, program production house, or public telecom organization; nor could CPB produce, schedule, or distribute programs to the public.^[35] At the same time, however, Congress maintained tight reigns on funding through the annual appropriations process.

Communications for National Security and Defense

Communication goals have evolved not only in response to changing social and economic needs. At times, they

have been radically reoriented to meet the exigencies of war. In most countries, reordering priorities for defense purposes was relatively easy. Owned and operated by the government, these companies were designed to serve the state's needs. In contrast, in the United States, in which the First Amendment precludes government interference, establishing a communication system to support national defense has been more problematic. To minimize the tension between defense and other communication-related goals, the government has involved itself in communications-related activities only on a sporadic and/or indirect basis.

This pattern was set at the time of the U.S. involvement in the First World War. In the autumn of 1918, for example, Congress directed the postmaster general to assume operation of the nation's telephone and telegraph companies. Under the post office's management, the telegraph and telephone systems worked smoothly, although rates increased. Shortly after the government took control, however, the war ended and Congress restored the wires to the private sector.^[36]

World War II and the Cold War that followed led to a much more compelling and pervasive preoccupation about national security. Although the government consistently turned to the private sector to promote its defense-related goals, an increased emphasis on national defense and security sometimes collided with those of free speech and a free market.

Limits on speech

Speech first became an issue during wartime with the passage of state and federal sedition laws, which were premised on the notion that speech could undermine the war effort. Early on, convictions were common because courts applied a "reasonable tendency" test. Later, justices began to fashion a standard that was more protective of free speech—the "clear and present danger" test, which cut off speech only if it posed an imminent and substantial danger to some vital interest.^[37] On rare occasions during peacetime, the government sought to enjoin the press from publishing information whose disclosure might undermine national security.

The government's attempt to invoke national security to stop publication of the *Pentagon Papers* failed when the Supreme Court, acknowledging that national security was sufficient reason to impose prior restraint on publication, ruled that in this instance the government had failed to show that anything more than embarrassment would result. In effect, the door was left ajar. Where atomic secrets have been involved, the government has been better positioned to justify a prior restraint. In 1970, for example, the government obtained a district court injunction that stopped publication of an article by *The Progressive* magazine, which depicted the making of a hydrogen bomb.

Promoting defense technology

Communication and information technologies have generally been high on the list of technologies meriting government promotion. Recognizing the defense potential of radio, for example, the government played a critical role in its development. The U.S. Navy, in cooperation with AT&T, not only helped to develop the emerging technology, it also spearheaded the corporate–government alliance to consolidate and centralize radio during and after World War II. The Wilson administration's goal was to challenge British domination of international communication and to protect U.S. military and commercial interests. After failing to get Congress to pass legislation that would make wartime government control of wireless permanent, the administration pursued a different strategy. In 1919, British Marconi was the only company negotiating with General Electric to buy exclusive right to the Alexanderson alternator, a high-powered radio transmitter used for transoceanic work during the war. Through a series of delicate negotiations, the government stepped in and served as the midwife to the birth of the Radio Corporation of America. RCA, with GE as the major stockholder, bought out Marconi (which had been controlled by the British), thus assuring America a powerful position in world communication (p. 70).^[9]

The military's role in developing the computer and other advanced communication technologies was also critical, even if indirect and behind the scenes. The government not only subsidized the early research and development of satellites, computers, and semiconductor chips, it also used its procurement powers to assure that these industries had stable, guaranteed markets.^[38,39]

Securing the infrastructure

The government's ability to balance government and free market interests was greatly aided by the existence of a government-regulated telephone monopoly, which was renowned for quality and research in all communications fields. As the only company supplying end-to-end telecommunications service to the Defense Communication Agency, AT&T was directly involved in formulating national security telecommunications specifications and requirements and in making adequate provisions governing robustness, ubiquity, and restorability. Nonetheless, believing AT&T's centralized, hierarchical structure to be vulnerable to attack, government researchers at the Advanced Research Project Agency developed a packet-switched network based on a decentralized architecture. By 1971, the ARPAnet—precursor to the Internet—linked defense scientists and engineers at 16 university-based nodes. To ensure their seamless and transparent interconnection, the Defense Department also sponsored two key networking standards: the transmission control protocol (TCP) and the Internet protocol (IP).

TRANSITION TO A COMPETITIVE ENVIRONMENT

As this short history illustrates, despite periods of upheaval and change, the U.S. communication policy regime—like the Constitution in which it is grounded—has proven to be quite flexible and stable over time. Old rules survived even as new ones were added. Multiple goals coexisted—even when they competed with one another—because each goal was associated with a particular communication technology having unique technical characteristics and imperatives as well as its own set of industry players. Thus, for example, First Amendment goals have generally been associated with print technologies, whereas universal service goals have been more closely linked to telephony and the transportation infrastructure. If—as was sometimes the case—the boundaries among technologies began to blur, policy makers intervened to reinforce the lines of demarcation.

Today, however, achieving flexibility in this way is increasingly problematic. Not only have new technologies been developed that do not fit neatly into old categories; with the convergence of print, carrier, and broadcasting technologies, old categories themselves no longer apply.

In light of such convergence, pressures have mounted to create a more level playing field and to establish a uniform regulatory regime based on market competition. As early as 1962, for example, a number of regulatory economists began to question the public utility concept. Together their work—if it did not give rise to the new deregulatory climate—served at least to legitimate it. As Roger Noll has described:

Economists generally entered the study of regulation with the naïve view that regulatory institutions were set up for the purpose of rectifying market failures. Unfortunately, and almost without exception, the early empirical studies—those commencing in the late 1950s and continuing into the 1970s—found the effects of regulation correlated poorly with the stated goals of regulation. By the early 1970s, the overwhelming majority of economists had reached consensus on two points. First, economic regulation did not succeed in protecting consumers against monopolies and indeed often served to create monopolies out of workable competitive industries or to protect monopolies against new firms seeking to challenge their position. Second in circumstances where market failures were of enduring importance (such as environmental protection) traditional standard-setting regulation was usually a far less effective remedy than the use of markets and incentives.^[40]

At the same time regulators, impressed by the potential of new technology to reduce costs and increase capacity, were also willing to experiment with competition. As former FCC Commissioner Nicholas Johnson commented on the occasion of the FCC's decision to approve MCI's application to establish long-distance service:

On this occasion three Commissioners are urging a perpetuation of more Government regulation of business, and four want to experiment with the market forces of American free private enterprise as an alternative to regulation. No one has ever suggested that Government regulation is a panacea for men's ills. It is a last resort: a patchwork remedy for the failings and special cases of the marketplace....I am not satisfied with the job the FCC has been doing. And I am still looking, at this juncture, for ways to add a little salt and pepper of competition to the rather tasteless stew of regulatory protection that this commission and Bell have cooked up.^[41]

Equally important, the growing importance of telecommunications and media-related industries within the economy changed the way communications came to be conceived. Instead of being perceived as a means to an end, communication was viewed increasingly as a commodity much like any other, to be bought and sold in the marketplace. In the process, the public interest came to be measured not by the quality of social and economic life, but rather by the state of the media industry and consumer demand.^[42]

Tensions and discrepancies within the old system first manifested themselves in the case of cable—a hybrid technology—but it was not long before they emerged in more traditional arenas such as telephony and broadcasting. Early attempts to address these tensions within the old regulatory framework were short-lived.

Fitting Cable into the Regulatory Regime

The inherent tension in broadcast regulation—between First Amendment rights and the public interest standard—became increasingly apparent with the advent of cable television, which did not fit well in either category. With its multiplicity of channels, cable was, moreover, the first technology to defy the long-held belief in scarcity.

Cable was originally intended to enhance television signals in communities located in areas outside good broadcasting reception. At first, the FCC ignored CATV, viewing it as an auxiliary to broadcasting. Seeking to avoid the administrative burden of regulating another industry, the FCC pointed out that CATV was neither a common carrier (because the subscriber did not determine the nature of the signal being carried) nor a form of broadcasting (because signal transmission was completely by wire). Thus, what attention the FCC did pay to CATV in the early years was centered on possible interference or problems for the broadcast sector. For a history of the FCC and the regulation of cable see.^[43]

The situation changed in the late 1960s, however, when cable operators sought to expand their markets by importing broadcast signals. Under pressure from broadcasters, the FCC issued rulings curtailing cable growth. Then in 1972 the FCC reversed itself, allowing cable to expand on the condition that it provided community

programming and adhere to must carry rules. Two factors served to stimulate industry's growth. First, the rise of pay-cable services such as Home Box Office revealed an extensive latent demand for alternative programming. Second and more important in the long run, cable programming became linked to satellite. Communication satellites created reliable and economically feasible distribution networks, while the availability of new and specialized programming stimulated nationwide demand.

As cable's fortunes improved and programming became available, operators characterized the industry as analogous to newspapers rather than broadcasting.^[44] On this basis, they called for deregulation and full First Amendment rights (See, e.g., Shapiro).^[45] Because spectrum scarcity had been used to justify broadcast regulation, cable's multichannel capacity lent credibility to its demands. As characterized by Laurence Tribe:^[46]

The clear failure of the 'technological scarcity argument' as applied to cable television amounts to an invitation to reconsider the tension between the Supreme Court's radically divergent approaches to the print and electronic media. Indeed, since the scarcity argument makes little sense as a basis for distinguishing newspapers from television even in the late 1960s and early 1970s, such reconsideration seems long overdue.

Seeking to rectify the situation, Congress passed the Cable Communications Policy Act of 1984, deregulating the cable industry. Nevertheless, considerable confusion about the nature of cable was embodied in the act itself. Cities lost the authority to regulate subscribers' rates and much of their discretion over franchise renewal. The act also prohibited the regulation of cable as a common carrier or public utility. At the same time, however, cities were allowed to charge franchise fees and require public access channels and other kinds of programming. The outcome represented as a compromise between the cities, which wanted to continue to charge franchise fees, and the cable operators, who wanted to facilitate the franchise-renewal process, but the compromise sidestepped the issue of the First Amendment.

Thus, the issue of cable regulation, and its relationship to the First Amendment, did not disappear. In fact, given rising cable prices and increased concentration, Congress reregulated the industry in 1992 under the Cable Television Consumer Protection and Competition Act. The new law reinstated rules for common carriage and rate of return regulation. In addition, it prohibited exclusive franchise agreements between cable and municipalities as well as affiliations between cable programmers and cable operators.

Subsequent court cases also failed to resolve the question of how cable should be handled from a regulatory perspective. In fact, while acknowledging that scarcity was no longer a problem, the courts—in the cases of

Turner I, Turner II, and Denver Area—upheld the must carry rules.^[47] Looking at the cable industry's structure and noting Congress' concerns about over-the-air broadcasting, the Court departed from a traditional doctrinaire interpretation of the First Amendment. As one critic of the decision characterized it:

In *Denver Area Educational Telecommunications Inc. v. FCC*, the plurality assiduously managed not only to avoid defining the First Amendment status of cable within fairly well-established boundaries, but seemed to grope at a new ad hoc constitutional approach somewhere between intermediate and strict scrutiny.^[48]

Instead it argued that First Amendment cases must be decided on a case-by-case basis and with reference to the context involved. Only by looking at the context, said the Court, is it possible to balance the vendor's First Amendment rights to provide information against the user's First Amendment right to access it.^[49]

Tensions in the Telecom Regime

As in the case of cable, technology advances helped to undermine the long-standing common carrier regime. Given the convergence of information and communication technologies, there was no longer a clear distinction between what constituted a monopoly (and hence regulated) service and what constituted a competitive service to be provided in the market. Convergence also gave rise to a new network architecture, in which intelligence was dispersed. As a result, the network could more easily be unbundled, allowing users to purchase, and new providers to offer, separate portions of it. Barriers to entry were also reduced, given technology advances that increased performance but greatly reduced costs.

Economic developments also generated incentives for new entrants. As information came to play a greater and more strategic role in business, large users sought alternative ways to meet their telecommunication needs. In some cases they set up their own internal networks. In others, they simply bypassed the Bell system, purchasing services in lower-priced, unregulated markets. Equally important from a political perspective, business users joined forces with burgeoning new service providers to press for greater competition.

In light of these developments, policy makers were more receptive to the idea of competition. In 1959, the FCC took a first step toward breaking up the Bell system with its "above 890" decision. This decision liberalized the licensing of private microwave systems, allowing the newly created Microwave Communications, Inc. (MCI) to offer a new product—discount private line service. With the subsequent Carterphone decision in 1969, the FCC opened the customer-premises market. Finally, with its Execunet decisions in 1976 and 1978 requiring AT&T to

connect to MCI, the FCC struck a final blow to the 100-year-old AT&T monopoly.

In 1982, AT&T entered into a consent decree with the Justice Department, following a decade-long antitrust suit. A modified final judgement (MFJ) went into effect in 1984, clarifying and expanding the terms of the 1982 consent decree. The basic premise of this divestiture was that the Bell system's competitive markets should be separated from their noncompetitive markets to prevent unfair monopoly abuses. Accordingly, AT&T was broken into eight companies, the reorganized AT&T and several regional holding companies. The Bell system's 22 local telephone companies were separated from the parent company, and grouped into seven regional Bell holding companies (RBOCs), which were prohibited from the three lines of businesses deemed competitive and therefore assigned to AT&T. These were designing and manufacturing telecommunications networks and customer premises equipment, providing information services (such as electronic yellow pages), and providing long-distance service.

While the MFJ settled the Department of Justice's antitrust suit, it could not resolve the tension between the goals of efficiency and competition that are inherent in any telecom regulatory policy. As Noll has emphasized,

Pending regulatory issues reflect an enduring characteristic of telecommunications policy; neither the pricing nor the structural issue has even been or is likely to be resolved. The telecommunications system is not, and never was, broken. Rather, its underlying technical and economic characteristics create an enduring policy dilemma. One can regulate prices and structure to encourage maximum feasible competition, or to promote an integrated monopoly. What is infeasible is a 'neutral' formulaic policy regarding prices and structure that will assure the right mix of monopoly and competition. The current policy agenda continues the futile search for better regulatory instruments, and also includes rear guard actions by the people who lost the last time around—who are not, and probably cannot be convinced that deregulated competition is the best policy (p. 233).^[39]

No sooner had the parties agreed to the MFJ when these issues re-emerged in the waiver process, the triennial review, and in public policy debates about how open the telephone network should be.

In this context, the FCC—eager to promote competition in the local exchange—devised a plan allowing RBOCs to enter new markets in exchange for opening their networks. To assure compliance, the local telephone companies had to make their basic network services (referred to as basic service elements) available in a uniform and nondiscriminatory fashion. Subsequently, in 1987 the ban against providing information services was amended, and then in 1991—following continued challenges by the RBOCs in court—all information service restrictions were eliminated. In an effort to promote innovation and greater competition

in the cable market, the FCC also established video dial tone rules that allowed local exchange companies to provide video services on a common carrier platform. None of the telephone companies saw it in their interest to pursue this option, however. Like cable companies, they wanted to be released from the yoke of regulation and to be brought within the First Amendment regime.

Efforts to Deregulate Broadcasting

Broadcasting had long been a target for deregulation. Challenges to the broadcast regulatory framework first got underway during President Carter's administration, when FCC chairman Charles Ferris initiated a deregulatory policy much in keeping with the administration's overall policy on deregulation. These efforts only achieved their full momentum, however, during the Reagan years, when Chairmen Mark Fowler and Dennis Patrick set out to revamp the entire regulatory structure, substituting marketplace constraints in place of regulatory controls.^[50]

Citing past FCC failures, opponents claimed that regulation was inappropriate for achieving broadcast policy goals, and at times counterproductive, as in the case of the FCC's efforts to constrain cable TV. Regulatory critics argued, moreover, that with the development of high-capacity cable scarcity no longer justified government intervention. Deregulation, they argued, was also more in keeping with First Amendment principles. Industry players echoed this claim, although they were much more pragmatic than principled in their enthusiasm, generally favoring only those measures that were economically advantageous.

To bring about a more competitive media market, the FCC began to undo the elaborate structure of rules and regulations that had been set up over the years.^[51] Thus the FCC eliminated most advertising constraints as well as rules requiring broadcasters to devote a given amount of time to different classes of nonentertainment programming—even fair use. At the same time, the agency relaxed a number of ownership rules.

Despite these changes, tensions persisted in broadcasting. Although broadcasters favored deregulation, they wanted to maintain the benefits, particularly access to free spectrum and the congressional favor that the public interest regime had afforded. Moreover, broadcasters could anticipate an even greater need for congressional support in the future, given the emergence of new technologies competing for spectrum. Relying heavily on broadcasters for financial and political advantages, members of Congress were also unwilling to unravel the public interest regime, thus there occurred the anomalous situation in which the FCC refused to enforce the Fairness Doctrine while key members of Congress championed it and promised to codify it at the first opportunity. As described by Le Duc, "At the moment, then, the broadcast deregulation has reached an impasse, Congress refuses to release the

commission from its obligation to regulate American broadcast service, while the agency refuses to discharge this obligation with any more diligence or dedication than absolutely required by law.”^[52]

THE TELECOMMUNICATIONS ACT OF 1996

Despite these tensions and mounting pressure for reform, efforts to fundamentally restructure the regulatory regime lacked an overriding vision and a set of guiding principles. Without such vision, reformers were unable to generate a broad political consensus in support of their efforts.^[53] As a result, reform proposals typically fell victim to the hassling and squabbles of the legislative process and to Congress’ reluctance to offend powerful interests. In the absence of legislative guidelines and in the face of rapid technology advance, decisions about communication policy were often regulated to the courts. It was only when Vice-President Gore successfully captured the unique potential of the Internet in his vision of a national information infrastructure (NII) that a groundswell for reform emerged.

The Internet Vision

The rapid rise of the Internet provided a unique opportunity as well as the necessary momentum to generate a new vision of communication policy for the future. Providing a digital platform for all forms of electronic communication, the Internet defied the technology and industry boundaries that had sustained three distinct regulatory regimes.

From a regulatory perspective, the most promising feature of the Internet was its open architecture and decentralized organizational structure. Viewed in these terms, the Internet could be best described as a very loosely coupled “network of networks.” Given common interfaces, networks on the Internet can be interconnected while they are at the same time operated and managed independently of one another, thus control is decentralized and horizontally structured. Given a common suite of protocols, interconnection is seamless, allowing traffic to flow easily and to be exchanged across disparate networks and applications. As described by the Computer Science and Telecommunications Board:

Most users of the Internet see it through experiencing its applications, most obviously the World Wide Web, but also the ubiquitous electronic mail, remote login, file transfer, and other applications. But from the perspective of Internet designers, the essence of the Internet is not the applications, but rather the more basic functionality that makes the Internet a suitable place for those applications to operate. The structure of the Internet reflects two major design objectives: first, to support as many sorts of applications as possible, and second, to operate over as many sorts of network infrastructures as possible.^[54]

According to this vision, in an Internet environment public policy goals could be achieved with minimal government interference (for this perspective, see McKnight).^[55] For example, with nonpropriety, widely available interfaces, interconnection and access would not be a problem, thus fostering competition and innovation. Moreover, diffusion would be rapid and widespread, given low costs and positive externalities resulting from shared provisioning and usage. Consumers also would be empowered. Because interoperability allows applications and intelligence to be unbundled and extended outward, individuals could control the provisioning and use of networks and applications.

When the Democrats came to power, Vice-President Gore incorporated this vision in the administration’s NII initiative, which was launched in September 1993. The initiative emphasized the hope of achieving broad-based social, economic, and political goals in the context of a competitive environment. The key principles included the need to: (1) encourage private investment, (2) promote and protect competition, (3) provide for open access to networks, (4) avoid the creation of a society of haves and have-nots, and (5) encourage network flexibility.^[56]

The NII initiative was intended not only to foster an open network architecture but also to provide a more open communication policy-making process. To support this process, the president established the Advisory Council on the National Information Infrastructure, which comprised 37 members—two-thirds from business and the remainder from the nonprofit sector, organized labor, and state and local government.^[57] Even more unprecedented, the government took advantage of the Internet itself to include the broader public in the debate.

The NII initiative served as a catalyst to bring together public interest groups and citizens who shared a common vision of a public-oriented infrastructure. In October 1993, they created the Telecommunications Round Table, a peak organization to lobby on behalf of their goals. Inspired by the Internet and the range of possibilities that it allowed, they called for a NII that would provide support for universal access, two-way communication, active and participatory public debate, competition and diversity of information, an equitable workplace, privacy protection, network security, and democratic policy making. While favoring market solutions, the coalition wanted proof of competition and consumer choice, as well as assurances that there would be no redlining, before government took steps to deregulate the industry. Equally important, they advocated that 20% of the bandwidth of the NII be reserved for public use as a public “right of way” (p. 328).^[57]

The national debate on the NII engendered enough momentum to break the congressional logjam, which had dashed all previous efforts at reform. Once the center of action shifted to Congress, however, the public interest groups generating this momentum had very little impact on the final legislative outcome.

The Missed Opportunity

Although the Communications Act of 1996 was generally welcomed as being long overdue, none of the parties to it was totally satisfied with the results. Arrived at through intense congressional lobbying, the law that was eventually adopted represented a carefully crafted compromise rather than a blueprint for the future. Concerned primarily that technology advance deprive them of some strategic competitive advantage, most key players ultimately preferred retrenchment to reform. A major opportunity was lost as a result.

Defeat in the 103rd Congress

In 1993, three bills relating to industry restructuring were introduced in Congress: the Brooks–Dingell bill (H.R. 3626), the Markey–Fields bill (H.R. 3636), and a companion bill in the Senate, the Hollings–Danforth bill (S 1822). Focusing primarily on industry deregulation, the Brooks–Dingell bill was the most narrow and permissive. As originally written, the bill called for a three-stage process of entry by which the local telephone companies could enter into long-distance services. Under pressure from the RBOCs, however the bill was modified to allow local telephone companies to seek authorization to enter long-distance from the Justice Department and the FCC on the same day the law took effect.

Strongly influenced by both the administration and increasingly vocal public interest coalition, the Markey–Fields bill went much further. Stressing the importance of an open network, the bill had much more stringent conditions for telephone company entry into other markets. According to the bill, local exchange carriers could enter other markets, but only after they had sufficiently opened up the local loop to competition. Telephone companies were also authorized to provide video services, but on a common carrier basis. In addition, the bill required the FCC to study the costs and benefits of the telephone companies providing an open network platform. At the same time, the Markey bill mandated open interfaces for set-top boxes and outlined steps to achieve social and economic goals, such as the provision of services to schools, health care centers, and libraries. In the summer of 1994, the House passed a somewhat watered-down version of H.R. 3636 by an overwhelming vote of 420 to 4, while the Senate moved to take up the companion bill, S 1822.

As fate would have it, a number of events intervened to bring Senate passage to an abrupt halt. The coalition supporting the legislation began to disintegrate in committee when Senator Daniel Inouye amended it, attaching S. 2195, which required carriers to allocate up to 20% of their capacity to noncommercial information suppliers in exchange for using public rights of way. This amendment was strongly opposed by industry players, who

successfully lobbied to reduce reserved bandwidth to 5%. The public interest coalition was similarly riled when Senator James Exxon introduced an amendment requiring the FCC to monitor and censor the Internet for pornographic materials. The final blow to the legislation, however, came when the RBOCs withdrew their support, protesting a provision that denied them access to competitive markets absent “actual and demonstrable” facilities-based competition. Unwilling to compromise on this point and faced with increasing Republican opposition, Senator Hollings, chairman of the Senate Commerce Committee and sponsor of the bill, allowed it to die in committee.^[57]

Retreat in the 104th Congress

In the November 1994 elections, Republicans returned to Congress with a mandate calling for deregulation. In keeping with the mood of the country, the leadership wanted to take immediate steps to deregulate the cable industry and greatly relax the limits on broadcast station ownership. Disagreements among industry players and concerns about a presidential veto made them more cautious,^[58] however. Although most members of industry were staunch supporters of deregulation and greater competition, they strongly disagreed about how best to achieve these goals. Long-distance carriers and cable operators, for example, called for more stringent prohibitions on local phone companies, while the RBOCs argued that competition was being impeded by MFJ restrictions. Broadcasters in turn contended that for competition to survive they needed free spectrum.

Faced with such difficult choices, the Republicans looked to industry to help them write reform legislation. With this objective in mind, they invited top industry CEOs to Washington to find out precisely what they wanted to incorporate in a bill.^[58] Hustling and jockeying for advantage continued right up to the end of the congressional debate. In the last six months before passage, for example, the top three long-distance companies contributed \$2.1 million in political campaign funds to member of Congress, while the seven regional Bells gave \$2.3 million.^[59] Not surprisingly in light of the outcome, the RBOCs favored the Republicans with their contributions, the long-distance carriers the Democrats. As reported in *Business Week*, changes in political fortunes had a significant impact on the flow of campaign funds. When the Democrats controlled the Congress, the money from political action committees was evenly divided between parties. In contrast, after the elections, the Republicans received \$1,267,122 while the Democrats received only \$473,289. Similarly, Congressmen who had the greatest political leverage in the telecom debate—such as Senator Larry Pressler, chairman of the Senate Commerce Committee—received the larger shares.”^[60]

The Legislative Outcome: Winners and Losers

Despite congressional gridlock over the budget, Republicans and Democrats joined together to pass the telecommunications reform legislation in early February 1996 by a vote of 414 to 16 in the House, and 91 to 5 in the Senate. On February 8, President Clinton, having originally threatened to veto the bill for being too lax, signed it into law. The stated purpose of the new legislation was to promote deregulation and competition. Hailed as a major step forward, the reform bill was essentially a well-honed bipartisan political compromise, providing some concessions to just about all. Sorely missing from the law, however, was an overriding vision of the role of communications in society and a clear set of principles linking deregulation and competition to a larger set of social and economic goals.

The stakeholder group that could perhaps be most pleased with the outcome was the RBOCs. Eager to enter the competitive fray, the RBOCs boycotted the previous Democratic-sponsored legislation on the grounds that it was too restrictive. The Republic legislation went much further in meeting their needs. According to the law, local telephone companies no longer had to prove the actual existence of facilities-based competition before entering competitive markets. Instead, they only need to gain approval of the FCC and state regulators based on a somewhat vague set of criteria outlined in the legislation.

For cable companies, there was also much to boast about. Four years previously, the FCC had ordered them to cut their rates by up to 17%. Under the 1996 act, all cable rates were to be deregulated after 3 years. In small communities, regulation ended immediately. With greater cash flow, cable companies could compete more easily in telephone company markets, and some companies were already upgrading their systems to provide phone service as well as consolidating their businesses to establish a better geographic fit with the telephone company markets.^[60]

The fate of the broadcasters under the new law was less certain. On the positive side, the law relaxed the previous cross-ownership rules, allowing broadcasters to own as many stations as they wanted as long as they did not exceed 35% of the U.S. market. Broadcasters failed, however, to eliminate a legislative provision requiring them to equip television sets with devices to block violent or sexual programs. Nor did broadcaster receive a clear mandate for free spectrum, as they had wished. Last-minute opposition from Senator Dole led to the postponement of this decision.

Nor did the long-distance companies fare as well as they had hoped. From their point of view, the longer RBOCs could be restrained from providing long-distance services the better. Given the status quo, long-distance carriers could gradually gain access to local exchange markets while local operating companies would still be

precluded from entering long-distance markets. The new legislation, which provided less stringent criteria for determining competition in the local loop, was thus generally viewed as a major setback.^[61] On the other hand, with the opening of the local loop to competition, long-distance carriers gained an opportunity not only to enter this lucrative market but also to bypass local exchange carriers by providing end-to-end services.

Society at large was perhaps the real loser in telecom reform. The primary focus of the bill was limited to deregulation and competition. Even when measured solely in terms of this narrow set of goals, however, the new legislation was sorely lacking. In contrast to the Markey bill, which had sought to promote open, two-way access, the Telecommunications Act eliminated most of the explicit requirements for interconnection and open interfaces. Instead of addressing the issue of competition head-on, it postponed the debate, delegating the thorny problems entailed in determining what constitutes "competition" to the FCC and the Department of Justice.^[62] Thus, for example, the law required the FCC to write no fewer than 80 rules determining how the transition to competition would take place and how the costs and benefits among industry players would be distributed.^[63,64]

Social considerations were not totally absent from the new legislation. For example, the act mandated the delivery of advanced telecommunications services to rural schools, libraries, and health care facilities at rates that are discounted to assure affordable access and use of such services. While reiterating the goal of universal service, however, the act charted a new course for achieving it. In contrast to earlier efforts, which relied almost exclusively on price averaging and other subsidies, the new legislation sought to achieve the goal of universal service—"to the extent technically feasible and economically reasonable"—in the context of a competitive market environment. The act also called for restrictions on content. It required television equipment providers to embed technological filtering devices—V-chips—into all new television sets, and Internet providers to monitor and censor content on the Web in order to prevent juveniles from accessing pornography.

The passage of telecom reform legislation in the United States was heralded as a major step forward in bringing communication policy into line with technology advances. Amidst the high-minded congratulatory statements and general sighs of relief, a few dissident voices could be heard. Focusing on the lack of competitive safeguards, these skeptics were concerned lest the law provide the means and incentives for the communications industry to reintegrate itself along vertical lines. Perhaps the most disturbing and prescient in this regard was the assessment of Judge Harold H. Green, who had overseen the 1984 consent decree governing the breakup of AT&T. As he confided

I'm a little concerned [whether] there are sufficient safeguards against the kinds of mergers and acquisitions that might give some small group of companies or individuals a strong hold over U.S. markets... I'd hate to see the AT&T monopoly be reconstituted in some form. It would be like I'd wasted the past 18 years.^[65]

Recent events and speculations about the future suggest that Judge Green's concerns were not without foundation.

COMPETITION IN RETROSPECT

The 1996 Telecom Act aimed to achieve a level playing field among industry players so that the market rather than government might effectively set the basis for interconnection among competing providers. The law, however, has proven much easier to write than to implement. Instead of promoting competition among communication services as was intended, it has led instead to a rash of mergers and the industry's reintegration. Equally discouraging, the promise of new, interindustry competition has dwindled as providers have begun to fully comprehend the costs and risks entailed in invading each other's markets.^[66] Not surprisingly under the circumstances, many consumers are now paying more for their phone and cable services than they did prior to the Act.^[67,68]

Nor has the Communications Act led to the deregulation of the communications industry or the demise of the FCC as so many of its proponents had hoped. To the contrary, in its effort to establish competition, the FCC had found it necessary to "reregulate," thus it had become more embroiled than ever in creating an elaborate set of detailed prescriptions to govern competition among the converging communication industries.^[69]

The problems entailed in implementing the 1996 act have been exacerbated not only by the high stakes involved and the complex and controversial nature of the issues, but also by the fact that the act itself left so much unresolved. To fulfill its mission, for example, the FCC was charged with carrying out three interrelated tasks: setting access charges, establishing the rule for interconnection, and establishing a mechanism for meeting universal service requirements. To meet the legislative requirement for nondiscriminatory access and pricing, in each case the FCC had to establish a means of determining real costs. The bane of all past regulatory proceedings, determining costs is anything but an exact science, and thus it has always been done in a somewhat arbitrary fashion. The problem of pricing is especially challenging in the case of universal service, given both the historical ties between pricing and universal service and the inherent tension between competition and universal service goals.

Given the uncertainties entailed in working out these issues, the FCC encountered political maneuverings and judicial litigation at every turn.^[70] No sooner had the Act

been passed, for example, when AT&T petitioned the FCC to bar the Bell companies from sharing market data with their out-of-region long-distance companies. Ameritech complained that Time-Warner's Home Box Office had refused voice and video on the Internet, competitive access providers complained that the RBOCs were holding up negotiations on access charges, and the Bell Companies contended that their competitors were using the regulatory process to block their entry into the long-distance market.^[63]

Disappointed by the FCC's performance, many have chastised the agency for overstepping its authority. Challenging the FCC's carrier interconnection order in court, for example, the states have claimed that the FCC lacks the authority to establish interim proxy prices or to prescribe the pricing methodologies that they might use. Politicians have similarly gotten involved, threatening to pass legislation constraining the FCC's future actions. By far the most outspoken legislator has been Senator John McCain, chairman of the Senate Commerce Committee. Proposing legislation to limit the FCC's role in determining antitrust cases, McCain has criticized the FCC in the following terms:

a majority of this Commission places too little confidence in competition and way too much in regulation. It tends to ignore the demands of making orderly, efficient, and fair decisions on the matters before it, preferring to pursue issues that are within neither their expertise nor their jurisdiction. It has shown a distressing tendency toward inconsistent and ad hoc decision-making, and toward picking and choosing which parts of the law it will choose to follow.^[71]

Market realities have also served to undermine the basic assumptions underlying the telecom act. Thus, for example, the act was based on the premise that the local loop was the only remaining network bottleneck. Today, however, with convergence and the development of Internet-based e-commerce, new bottlenecks have appeared. By integrating infrastructure services and applications, providers can benefit not only from economies of scale and scope, but also from the many positive externalities associated with networked technologies. Equally important, integrated networks command higher service prices because businesses need a seamless networking platform to link their operations. In addition, by offering an integrated platform, providers can gain a first-mover advantage using the network as a barrier to entry. Offering a wide range of business services, they can also position themselves best to collect and make optimal use of transactional data. Perhaps the best example continues to be Microsoft. Building upon the Internet, Microsoft has pieced together an entire suite of business applications, ranging from accounting to procurement.^[72]

Not surprisingly, network providers are scurrying to take advantage of these opportunities. Mergers and

acquisitions in information technology, communication, and media industries jumped 97% in 1997, to \$488 billion.^[73] Nor are Internet companies immune to these developments. In fact, given the lack of barriers to market entry, they are far more inclined to engage in mergers and acquisitions than established lower tech companies. As noted by one consulting firm, for the top 25 Internet companies, the average number of years before significant merger and acquisition activity take place is 6 years, as compared to 72 years for the top 50 U.S. companies.^[74]

This kind of integration will not be limited to large-scale infrastructure industries. As described by Hof

That could prove all the more true thanks to a rapidly emerging new class of net middlemen in a wide range of consumer and industrial markets. Online, with few limitations of time and geography, these new market makers can quickly generate a virtuous loop of buyers and sellers whose very presence attracts yet more buyers and sellers. For this reason, they're expected to dominate many industries from chemical suppliers to rolled steel.^[75]

Equally disturbing, where competition among providers has been rampant, it has had major unintended consequences. Thus, for example, network providers competing to be the first to fiber the country have generated a major glut in capacity. According to one source, these companies spent \$90 billion to lay approximately 39 million miles of fiber optic cable, of which only 2.6% is in use. Not surprisingly, many of these companies are verging on bankruptcy.^[76] The failure of these companies has taken a major toll on related industries, such as equipment manufacturers, venture capital, and the stock market.^[77] As the author notes:

Nearly every technology sector is linked with telecom: phone companies buy networking equipment to route Internet traffic, computer servers to offer Web hosting, software to dish up services, and fiber-optic gear to transport bits of information. Last year, spending on communications gear in the U.S. totaled \$124 billion, or 12% of business spending on equipment and software, according to the Commerce Department. Moreover, it accounted for one-quarter of the rise in business spending (p. 102).^[77]

The impact on the economy as a whole has yet to be measured. Estimates are that the recession generated by the collapse of the high-tech sector may not show signs of recovery till late 2002.

THE MARKET AS MEDIATOR

Much of the criticism of the Telecom Act of 1996 has been directed at the problems and side effects associated with its implementation. Over the long term, however, even more serious problems are likely to emerge, which

cannot be mediated within the framework of a competitive marketplace. The market works best to allocate resources when such resources are fungible; that is to say, when their values can be reduced to an equivalency or common denominator. Notwithstanding recent efforts by policy makers and industry stakeholders to characterize communication as a commodity, communication resources are highly problematic in this regard. For example, harking back to former Chairman Fowler's comparison of television and toasters, the present chairman of the FCC—William Powell—recently analogized the “digital divide” to the inequities associated with car buying.

One need only consider, for instance, the multifaceted nature of communication. Communication resources serve not only to meet consumer needs but also social and economic goals, which are much more difficult to measure adequately. Often the prices consumers are willing to pay for communication as a commodity diverge significantly from its social and economic value. Declining public support for the First Amendment provides a case in point. Notwithstanding the First Amendment's central role in the U.S. political system, a growing number of Americans now believe that the media has “too much freedom.” A recent survey conducted by the First Amendment Center found, for example, that 39% of the respondents believed the First Amendment “goes too far in guaranteeing rights, compared with slightly more than 22% last year.”^[79] Imagine how much less support there would be if consumers were called upon to pay for this freedom directly!

Compounding the problem of measurement is the fact that the value of communication is not constant. To the contrary, it is highly dependent on time and circumstances. As the survey of U.S. communication goals clearly illustrates, the priorities that policy makers give to certain communication goals and the way in which they seek to implement them are highly contingent on historical conditions and the social and economic problems that loom large at the time. Thus just as the Founding Fathers' reluctance to involve government in media affairs is traceable to their experiences during the Revolutionary War, so too the government's willingness to take a more proactive approach in the latter half of the 1800s can be attributed in part to the perceived need to heal the wounds left by the Civil War.

We should expect no less today. As our social and economic circumstances change, new tensions and problems that call for communication-related policy responses are likely to emerge. Certainly, for example, the rise of Web-based networked commerce will provide a major stimulus in this respect. With the convergence of networks, markets, and firms, issues that were at one time clearly situated in the realm of economic policy will become enmeshed with those in the realm of communications.^[79] Already a number of privacy issues are emerging that span these two realms. According to one recent industry-sponsored study, new privacy rules will cost industry

between \$9 billion to \$36 billion.^[80] Other likely candidates include issues related to taxation, licensing, property rights, and antitrust. Crosscutting issues in the area of defense and security are also likely, given the decentralized nature of the Internet and the ability to circumvent traditional lines of authority.

Globalization will also present new policy problems and choices. As the World Trade Organization conflict over audiovisual content makes clear, the task of valuing communication resources and making trade-offs among communication-related goals is greatly exacerbated by cross-cultural differences. Whereas U.S. policy makers consider audiovisual materials to be commodities that should be freely traded, Canadians and French policy makers view them as a cultural heritage to be protected and supported by government. Even when there is general agreement among countries with respect to goals, policy makers may interpret goals differently and/or choose alternative ways of implementing them. Whereas in the United States, for example, antitrust decisions are typically determined based on the potential harm to consumers, in Europe they are decided based on the potential harm to competitors.

In a capitalist society, the market mechanism will always play an important role in sorting out communication policy issues. As the history of U.S. communication policy makes clear, however, the market is only one among several policy tools that government can call upon to implement its goals. In fact, by employing different policy mechanisms in the past, the government was able to avoid making difficult trade-offs among competing goals; freedom of expression, ubiquitous infrastructure deployment, and education could all be accommodated. Conflicts among policy goals are likely to be even greater in the future, given the enhanced role of communications and information in all respects of life. To resolve emergent communication issues while taking full responsibility for our choices, we cannot simply defer to the marketplace. In addition to its role as "market maker," government must—depending on the circumstances—continue to play the supporting roles of broker, educator, regulatory, and promoter.

Community Informatics

Kate Williams

University of Illinois at Urbana-Champaign, Champaign, Illinois, U.S.A.

Joan C. Durrance

School of Information, University of Michigan, Ann Arbor, Michigan, U.S.A.

Abstract

Community informatics is an emerging field focusing primarily on the interaction between local communities and information technologies and a more particular focus within social informatics. It is rooted in library practice, most notably the outreach that led to information and referral (I&R) services, as well as other innovative practices, for example the community technology center and the community network, aimed at strengthening communities faced with the digital era and its attendant disruptions and opportunities. Community informatics research and teaching is carried out at a growing number of library/information schools and elsewhere, as appropriate to this interdisciplinary endeavor.

Community informatics is an emerging field that encompasses both study and practice, although the focus here is on the former. Loader (2000, cited in Keeble)^[1] has described it as navigating the interaction between *transformation* as expressed in information technology and *continuity* as expressed in a local, historical community. This is a specification of Kling's definition of the field of social informatics, of which community informatics is a part: "the interdisciplinary study of the design, uses and consequences of information technologies that takes into account their interaction with institutional and cultural contexts."^[2] While social informatics historically most often concerned itself with business and government settings, community informatics looks at a third realm of social activity, the community. The concept of community and the tensions within that concept, set in the context of the nascent information society, are the basis for the core ideas of community informatics. Community informatics practitioners can be found in public libraries, community technology centers, community networks, and in an increasing range of community and economic development activities, employed in the private, public, or non-profit sectors. Researchers come from the disciplines of library and information science, communications, community development, computer science, informatics, sociology, urban and regional planning, and other fields. Fortunately, the discussion in this encyclopedia entry is informed by the fact that one author (Durrance) comes to community informatics through library practice and scholarship, and the other through community practice and study of the digitization of society, or social informatics (for example, see Williams).^[3] This allows the entry to trace multiple paths that have led to a single, if fuzzy-bounded, interdisciplinary field. By all accounts,

however, the starting point is very much the local, historical community.

COMMUNITY AS THE BASIS FOR COMMUNITY INFORMATICS

Most scholars have defined information technology very concretely as a particular, if evolving, set of digital tools and applications. But defining and understanding community is a challenge that has productively engaged more than a century of scholars. With the last major wave of U. S. migration from country to city, the fate of community within the metropolis occupied a generation of scholars, who themselves referenced the scholarship of those who had earlier grappled with the meaning of the European migration to the cities. The earlier discourse was very much driven by the ideas of Marx, Tönnies, and Durkheim, while the Chicago School (including among others Frazier, Mead, Park, and Wirth) was the most influential in the United States.

Community is variously defined in the social sciences and has been examined in many of its guises in community informatics literature. Most often, it refers to a population living within certain geographic boundaries (geographic community), and this gives rise to a local history and culture which is the context for whatever else happens. This definition is bolstered by the fact that planning and funds flows are channeled according to those boundaries and political battles are often fought within these jurisdictions. This can be seen during the 1980s when various cities implemented community technology projects. (For a comparison of four cities, see Guthrie).^[4]

But there can be communities within these geographic communities, as for instance the communities of interest that contended—homeless and their allies, and local business and real estate interests—within Santa Monica's Public Electronic Network.^[5] Or Bishop et al.'s^[6] work on a Web tool for local African-American women working on health issues. And there are communities with a particular geographic, historical origin that are now spread across large or small distances. Diasporic communities have taken to the Internet to maintain close ties with people far away, for example Trinidadians.^[7] And one's community may be spread across a single metropolis, as in Wellman.^[8] Wellman, in fact, later proposed^[9] and then tempered his assessment^[10] that every individual with their ties now represents a distinct personal community, more or less place-based.

Benjamin^[11] used a recursive definition of community—"people living in a geospatial area who define themselves as part of a community"—in order to analyze why some telecenters succeed and others fail to attract local involvement. This definition has a history in ethnography and acknowledges that communities are quite often self-identified or socially identified.

Human activity itself has been theorized as taking place in communities.^[12] Rheingold documented the arrival of the virtual community^[13] and the cell phone based social network.^[14] Rheingold's online or phone based communities interact in particular ways with the local, the historical community. Online discussion lists, games, and other social computing phenomena have generated interesting work that enriches and is enriched by community informatics per se.

There are tensions and overlaps between these various communities. The field of community informatics, by studying the interaction between transformation and continuity, between information technology and local community, is building up a picture of how the social, historical places we live in are evolving as we move from the industrial age to the information age, with particular attention to social and digital inequalities. Moreover, it has done this very much based on practice, both inside and beyond libraries.

ROOTS OF THE FIELD OUTSIDE THE LIBRARY: THE SOCIAL INFORMATICS PERSPECTIVE

Setting aside for the moment the important role of libraries and library scholars in community informatics, several other interrelated but distinct social trends have also given rise to and continue to shape the field. These can be summed up as the network society, the hacker ethic, and the digital divide.

For some time now the network society has been unfolding on and in local communities. What does this term mean? It means that today society is characterized

by networks rather than organizations; flexible production with a flexible workforce; an economy that is globally coordinated in real (or chosen, as with e-mail) time. A new space has been identified that contrasts with the space of place, that is, the geographic communities where we live and breathe. This new space is the space of flows that is based on digital tools and systems; in other words, the sum total of all the communications and transportation flows that link the global, mobile, network of human networks.^[15] The world's economies, east and west, adopted digital technologies even as they experienced the economic crises of the 1960s and 1970s; what has resulted is spaces of place that are threatened, because they are mostly bypassed, by the space of flows. In the industrialized countries, one can think for example of Rust Belt, United States or vast stretches of the North of England as thus threatened. Other spaces of place, Silicon Valley, for example, have certainly not been bypassed, and yet even there the space of flows has left toxic dumps for the space of place to cope with.

Faced with this, local governments responded with digital initiatives of their own. Among many: In 1989, Santa Monica, California, offered its residents free online discussion lists, accessible in public libraries or from home, and access to city officials, as mentioned above.^[16] In 2000, Lagrange, Georgia, offered its entire population free cable Internet.^[17]

An interesting reflection in academia of this space of place-space of flows or network-communities tension was the 1996 colloquium that became the edited volume *High Technology and Low Income Communities*.^[18] This arose from a dialogue between two mutually exclusive groups in urban planning at MIT, one focused on opportunities for Information and Communication Technology (ICT) and the other on low-income communities. They recruited Manuel Castells to the event and produced a proceedings volume that discussed, but did not name, community informatics.

On the heels of early experimentation, the second social trend that has given rise to community informatics is the discourse and the activity around the concept of the digital divide. This emerged in the mid 1990s as a popular phrase for the gap between people who access and use information technology and those who do not.^[19] In the United States, the Department of Commerce was an early implementer of both research and policy on this. The department launched a (continuing) series of survey reports on individuals' access to and use of computers and later the Internet and other particular tools such as cell phones.

In the realm of practice, the same agency within the Department of Commerce began more than a decade of annual rounds of grantmaking (Telecommunications and Information Infrastructure Assistance Program (TIAP), later the Technology Opportunities Program, or TOP) to organizations in local communities to support their community technology projects. The Department of Commerce

initiative was rooted in the economic imperative to develop a market for computers and for e-business and to develop a skilled workforce via education and public provision of information technology. Such experiments as TOP were echoed by private and other public funders, including technology companies and even the National Science Foundation, which helped Playing to Win launch the nationwide Community Technology Centers Network. One could certainly say that the dot-com technology bubble fueled the digital divide discourse in the United States, with corporations supporting local and national projects.

A third social trend giving rise to community informatics can be summed up as the hacker ethic, which took hold as computers and software became a hobby and a profession. In contrast to the media's definition of hacker as thief, the hacker ethic is the practice of building computers and writing code for the fun of it, for the creativity of it, and for the community-building. This is what^[20] calls "the spirit of the information age." The hacker ethic expressed itself in the origins of the personal computer out of the milieu of the Homebrew Computer Club and in the production of Linux and other such software. It also expressed itself in projects where hackers joined up with others to produce tools such as:

- PLATO, where by 1972 hackers and teachers were writing online courses for all levels of students.^[21]
- Berkeley Community Memory, the public terminals established in 1973 that provided an online bulletin board for all passers by.^[22]
- Community technology centers such as Playing to Win, opened in 1983 by math teacher Antonia Stone in a Harlem housing project,^[58] and
- Freenets or community networks such as the Cleveland Free-net, which began life in 1984 as St. Silicon's Hospital and Information Dispensary, an online communications tool for doctors and patients.^[23]

The community network and community technology center phenomena each grew into international movements, with associations, publications, and annual conferences for practitioners. Community technology projects emerged out of the grassroots—as in Toledo, Ohio^[24–27] and inner-city Wilmington, North Carolina^[28]—and blossomed in both virtual and actual space. Community network developers soon connected with librarians and library scholars, for reasons given below.

ROOTS OF THE FIELD WITHIN LIBRARIES

Urban social unrest provided the backdrop for librarians developing new approaches to service that resulted in the creation of early community information services. The riots of the late 1960s marked the beginning of change in the nation's urban libraries. The decay of the inner city

had resulted in a mismatch between the services that agencies such as public libraries offered in the mid-1960s and the needs of a changing population. Librarians had traditionally used library circulation figures to measure their effectiveness in the community. As the middle class left the nation's major cities, urban libraries suffered a drastic drop in circulation. At the same time researchers found that, "citizens are uninformed about public and private resources, facilities, rights, and programs. . . and frustrated in their attempts to get information required for everyday problem solving" (p. 20).^[29]

By the early 1970s, the federal government had provided funding for both the development of information and referral (I&R) services and a series of educational programs and guides aimed at helping professionals gain skills in developing I&R services.^[30–32] The federal government's active fostering of the development of I&R services by various institutions drew in both practitioners and academics, including a group of pioneering urban libraries and a small cadre of LIS (library and information science) researchers.^[29,33,34]

Academics who focused on community information in the 1970s worked with practitioners through associations and consultancies, analyzed practice, contributed articles and reports, made public presentations and developed academic curricula in the established LIS programs at Syracuse University, the University of Maryland, Drexel University, and the Community Specialist Program at the University of Toledo.

Clara Jones, then Director of the Detroit Public Library and its first African-American leader, argued at the time that:

The welfare of the public library is inextricably interwoven with the destiny of the city, the financial dilemma of libraries being one manifestation of characteristic urban ills. Although we are a predominantly urban nation, there is widespread indifference or resignation to the desperate plight of cities. . . It seems increasingly evident that we can no longer depend solely on the traditional cornerstone of public library service to adults—reference work, reading guidance, and programming—to stimulate sufficient interest and satisfy a broad enough range of needs (pp. 85–86).^[35]

The purpose of I&R was to provide a link between a person with a need and the resources in the community that would meet that need. To accomplish this, pioneering I&R staff created community information files, provided information about community services, and engaged in active question negotiation. Information and referral services, considered essential to avoid fruitless agency ping-pong—people seeking services bouncing from one office to the next in an environment where social services by hundreds of agencies and nonprofit organizations were delivering social services. Information and referral work was considered by many to be a radical departure from standard public library services.

At their outset, I&R services were also confusing and lacked definition.^[33] The Alliance for Information & Referral Services in 1973 defined I&R and outlined a set of activities including: file development, simple and complex information giving, actively helping clients make contact with a resource (referral), working with the client to overcome obstacles (advocacy), and assuring that clients actually reached the appropriate resources (follow-up); some of these were divergent from traditional library practice. In the late 1970s, Childers conducted a benchmark study of I&R in public libraries and found that while public libraries in his study embraced the information role, for the most part they did not engage in referral and follow-up.^[33]

In spite of the limitations in adopting the I&R model in the 1970s, library engagement in the community-focused information services discussed above laid the groundwork for the public library's community-focused roles in the digital age and the beginnings of academic response to community problems.

By the 1990s, librarians and library scholars were ready to join forces with the grassroots activists, local government staffers, foundations and other nonprofits, and businesses who were experimenting with technology in communities. A particular series of three conferences helped to catalyze the community networking movement. The Ties that Bind conferences (1994, 1995, 1996) were sponsored by Apple Computer's Library of Tomorrow Project and the Morino Foundation. They brought together a wide range of individuals and groups to foster community networking.^[36] The encompassing goals of these conferences were:

to provide information and case studies on the types of community networks that have proven viable, including economic, collaborative, and technical models; to help individuals representing schools, non-profits, foundations, businesses, media, and government agencies realize how community networking can be used as a tool to help advance the goals and needs of the community; to understand the importance of community networking in the formation and effective use of the National Information Infrastructure; to understand the emerging context – the social, economic, technical political, and sustainability issues which characterize the challenges and potentials for Community Networking.^[37]

These conferences, led by Steve Cisler of the Apple Library of Tomorrow, resulted in the creation of the Association for Community Networking and strongly influenced the encompassing thought processes that resulted in the development of the community informatics framework.

A major study funded by Institute of Museum and Library Services (IMLS) and conducted in 1999–2000 by Durrance & Pettigrew found that community information provision had undergone major change as a result of Internet adoption by libraries. They found increased use of networked community information, a variety of

digitization projects, a strong Internet presence, adoption of digital reference, increased collaboration between libraries and other community organizations, and, as a result of these innovations, increased visibility and community support.^[38,39]

One noteworthy example of library-community information projects is the Tallahassee FreeNet (TFN), Florida's oldest community network. It was started in 1993 by faculty from the Florida State University super-computer center. Quickly the LeRoy Collins Leon County Public Library became an operating partner and the TFN became one of the nation's first library-university community networking projects. Tallahassee FreeNet's mission statement reflected the aims of all the early collaborative community networks:

TFN is more than an operator of an information system. It is the agent guiding Tallahassee and to some extent Florida, into the Information Age. Therefore, it is further the mission of TFN to precipitate community cooperation that is the basis for having community-wide electronic communication.^[40]

University Contributions

During the 1990s, a number of universities, armed with excess computing power and aware of the digital disparities between the universities and communities, worked with local agencies to form community networks. Several of the long-lived projects among these are worth noting:

1. The Community Networking Initiative (later joined with the Alliance for Community Technology) at the University of Michigan School of Information and Library Studies, now School of Information. The University of Michigan Community Networking Initiative (UM-CNI) began with support from the W. K. Kellogg Foundation in 1994. This project enabled faculty and students to take a leadership role in Internet-based community networking (see, for example, Durrance).^[41] A collaborative venture involving the UM-CNI, the Flint Public Library, the Mideastern Michigan Library Cooperative, the Library of Michigan, and the Apple Library of Tomorrow Program created in 1995 the Flint Community Networking Initiative, a model public library Internet training laboratory featuring an extensive training program first for staff and later for community members—especially teens—and an ongoing community-focused Internet presence in Flint. Today the Alliance for Community Technology carries out a variety of teaching, research, and service projects.
2. PrairieNet and the Community Informatics Initiative at the University of Illinois at Urbana-Champaign Graduate School of Library and Information Science. PrairieNet, a partnership between the university and

local community members and nonprofit organizations, was founded in 1993. It seeks to:

promote equity of access to computer resources for everyone in the community; facilitate information and resource sharing in support of community development efforts; empower individuals by teaching computer skills and providing access to the Internet; and strengthen community organizations by assisting them with access and the sharing of information.^[42]

The Community Informatics Institute focuses on research and teaching, especially through Prairienet and its other community partnerships, among them the East St. Louis Action Research Project and the Puerto Rican Cultural Center in Chicago.^[43,44]

3. Blacksburg Electronic Village at the Virginia Polytechnic Institute and State University. This program is connected to researchers in architecture and design (and later information architecture) as well as human-computer interaction. This collaboration included the Town of Blacksburg and a major communication company in order to bring high-speed Internet and social computing to the community. Planning began in 1991; the Blacksburg Electronic Village became operational in 1993. It has been an international model for networked community through its innovative collaboration and citizen involvement.^[45]

EMERGENCE OF COMMUNITY INFORMATICS AS A UNIFYING CONCEPT

Allowing for the caveats summed up by Stoecker,^[46] a loose network of scholars can today be seen to comprise a core of community informatics research. The scaffolding of the field features two processes that have contributed to drawing together scholars via conferences, proceedings volumes, and at least one journal. The first of these two processes is the series of seven Dimensions in Advanced Computing (DIAC) conferences sponsored by Computer Programmers (later Professionals) for Social Responsibility since 1987; this has generated both proceedings volumes and edited books (most recently Day and Schuler^[47] and Schuler and Day).^[48] Dimensions in Advanced Computing's organizer Doug Schuler, a cofounder of Seattle Community Network, launched an undergraduate program in community informatics and authored *New Community Networks: Wired for Change*.^[49]

The second process has been anchored in the north of England, where Brian Loader and others have generated a flow of edited and authored volumes,^[1,50-55] several conferences, and the quarterly journal *Information, Communication and Society* (since 1998), all while guiding several community technology projects.

Other integrative processes are: 1) the work of^[56] defining community informatics and bringing particular

attention to work in Australia, Canada, and elsewhere; 2) the annual Community Informatics Research Network meetings; 3) the broader biennial Conference on Communities and Technologies; 4) the also more broad but still highly useful conferences of the Association for Internet Research (annual since 2000) and 5) the journals *First Monday* (launched 1996), *The Information Society* (1981), *Journal of Computer Mediated Communication* (1995), *New Media and Society* (1999), and the *Journal of Community Informatics* (2004).

NEW DIRECTIONS

As technology has evolved, converged, and diffused, the binary concept of the digital divide has revealed itself as containing multiple digital *inequalities* bearing deeper analysis. (For a recent example see Mossberger).^[57] Four trends are worth noting: datasets, globalization, a turn towards theory, and a recent expansion of community informatics curriculum in library information science schools.

First, academic and policy researchers have produced hundreds of case studies, and the color and texture of these continue to be highly valuable. The multitude of studied and not-yet-studied community informatics projects and practices and the need for research to guide policy present scholars with an opportunity to standardize our approach to case studies and to collect and analyze larger datasets. This will allow us to generalize and confirm trends in communities. Second, related to this, is the imperative to study community technology as a global phenomenon rather than a national one. The search for community development through technology, for community sustainability in the digital age, is turning up lessons in one part of the world that others cannot afford to ignore.

Third, as researchers turn increasingly to theorizing as well as describing, our work on communities can be usefully placed alongside the work of others on the informatics of our government, education, and business sectors. A number of theoretical concepts and frameworks are already proving powerful in this regard: information use, community inquiry, civic intelligence, social networks and social capital,^[59] and the public sphere among them. These summations will help community informatics and others scholars to revisit and update our conceptions of the Information Society, which first took shape with very little actual data from the localities where we all live.

A fourth trend is not within the research but relies on it: the expansion of community informatics and community information in the curricula of the library and information science schools. The iSchools conferences are playing a role here; offering sessions focusing on community informatics. Today courses in this area are taught at the graduate level at 7 of the 57 library and information science programs in the United States and Canada. It is expected that Gurstein such efforts will grow, in and beyond the LIS programs.

Complexity and Self-Organization

Francis Heylighen

Free University of Brussels, Brussels, Belgium

Abstract

This entry introduces some of the main concepts and methods of the science studying complex, self-organizing systems, and networks, in a nontechnical manner. Complexity cannot be strictly defined, only situated in between order and disorder. A complex system is typically modeled as a collection of interacting agents, representing components as diverse as people, cells, or molecules. Because of the nonlinearity of the interactions, the overall system evolution is to an important degree unpredictable and uncontrollable. However, the system tends to self-organize, in the sense that local interactions eventually produce global coordination and synergy. The resulting structure can in many cases be modeled as a network, with stabilized interactions functioning as links connecting the agents. Such complex, self-organized networks typically exhibit the properties of clustering, being scale-free, and forming a small world. These ideas have obvious applications in information science when studying networks of authors and their publications.

INTRODUCTION

A new paradigm for scientific inquiry has been emerging: complexity. Classical science, as exemplified by Newtonian mechanics, is essentially reductionist: it reduces all complex phenomena to their simplest components, and then tries to describe these components in a complete, objective, and deterministic manner.^[1,2] The philosophy of complexity is that this is in general impossible: complex systems, such as organisms, societies, or the Internet, have properties—emergent properties—that cannot be reduced to the mere properties of their parts. Moreover, the behavior of these systems has aspects that are intrinsically unpredictable and uncontrollable, and cannot be described in any complete manner. At best, we can find certain statistical regularities in their quantitative features, or understand their qualitative behavior through metaphors, models, and computer simulations.

While these observations are mostly negative, emphasizing the traditional qualities that complex systems lack, these systems also have a number of surprisingly positive features, such as flexibility, autonomy, and robustness, that traditional mechanistic systems lack. These qualities can all be seen as aspects of the process of self-organization that typifies complex systems: these systems spontaneously organize themselves so as to better cope with various internal and external perturbations and conflicts. This allows them to evolve and adapt to a constantly changing environment.

Processes of self-organization literally create order out of disorder.^[1] They are responsible for most of the patterns, structures, and orderly arrangements that we find in the natural world, and many of those in the realms of mind, society, and culture. The aim of information science

can be seen as finding or creating such patterns in the immense amount of data that we are confronted with. Initially, patterns used to organize information were simple and orderly, such as “flat” databases in which items were ordered alphabetically by author’s name or title, or hierarchically organized subject indices where each item was assigned to a fixed category. Present-day information systems, such as the World Wide Web, are much less orderly, and may appear chaotic in comparison. Yet, being a result of self-organization, the Web possesses a nontrivial structure that potentially makes information retrieval much more efficient. This structure and others have recently been investigated in the science of networks, which can be seen as part of the sciences of complexity and self-organization.

The concept of self-organization was first proposed by the cyberneticist W. Ross Ashby^[3] in the 1940s and developed among others by his colleague Heinz von Foerster.^[4] During the 1960s and 1970s, the idea was picked up by physicists and chemists studying phase transitions and other phenomena of spontaneous ordering of molecules and particles. These include Ilya Prigogine,^[1] who received a Nobel Prize for his investigation of self-organizing “dissipative structures,” and Hermann Haken,^[5] who dubbed his approach “synergetics.” In the 1980s, this tradition cross-fertilized with the emerging mathematics of nonlinear dynamics and chaos, producing an investigation of complex systems that is mostly quantitative, mathematical, and practiced by physicists. However, the same period saw the appearance of a parallel tradition of “complex adaptive systems,”^[6] associated with the newly founded Santa Fe Institute for the sciences of complexity, that is closer in spirit to the cybernetic roots of the field. Building on the work of John Holland, Stuart Kauffman,

Robert Axelrod, Brian Arthur, and other SFI associates, this approach is more qualitative and rooted in computer simulation. It took its inspiration more from biology and the social sciences than from physics and chemistry, thus helping to create the new disciplines of *artificial life* and *social simulation*. The remainder of this entry will mostly focus on this second, simulation-based tradition, because it is most applicable to the intrinsically social and cognitive processes that produce the systems studied by information science. Although the other, mathematical tradition sometimes uses the term “complex systems” to characterize itself, the labels of “nonlinear systems” or “chaos theory” seem more appropriate, given that this tradition is still rooted in the Newtonian assumption that apparently complex behavior can be reduced to simple, deterministic dynamics—an assumption which may be applicable to the weather, but not to the evolution of a real-world social system. Extending both traditions, the turn of the century witnessed a surging popularity of research into complex networks. This was inspired mostly by the growth of the World Wide Web and the models proposed by Watts and Strogatz,^[7] and Barabasi and Albert.^[8]

At present, the “science of complexity” taken as whole is still little more than a collection of exemplars, methods, and metaphors for modeling complex, self-organizing systems. However, while it still lacks integrated theoretical foundations, it has developed a number of widely applicable, fundamental concepts and paradigms that help us to better understand both the challenges and opportunities of complex systems. This entry will try to introduce the most important of these concepts in a simple and coherent manner, with an emphasis on the ones that may help us to understand the organization of networks of information sources.

COMPLEX SYSTEMS

There is no generally accepted definition of complexity.^[9] different authors have proposed dozens of measures or conceptions, none of which captures all the intuitive aspects of the concept, while they are applicable only to a very limited type of phenomena, such as binary strings or genomes. For example, the best-known measure, “Kolmogorov complexity,” which is the basis of algorithmic information theory, defines the complexity of a string of characters as the length of the shortest program that can generate that string. However, this implies that random strings are maximally complex, since they allow no description shorter than the string itself. This contradicts our intuition that random systems are not truly complex. A number of more complex variations on this definition have been proposed to tackle this issue, but they still suffer from the fact that they are only applicable to strings, not to real-world systems. Moreover, it has been proven that

the “shortest possible” description is in general uncomputable, implying that we can never be sure that we really have determined the true complexity of a string.

In spite of these fundamental problems in formalizing the notion of complexity, there are a number of more intuitive features of complex systems that appear again and again in the different attempts to characterize the domain.^[2] One that is more or less universally accepted is that complexity must be situated *in between order and disorder*: complex systems are neither regular and predictable (like the rigid, “frozen” arrangement of molecules in a crystal), nor random and chaotic (like the ever-changing configuration of molecules in a gas). They exhibit a mixture of both dimensions, being roughly predictable in some aspects, surprising and unpredictable in others. This intermediate position, balancing between rigidity and turbulence, is sometimes called the “edge of chaos.” A number of theorists have proposed that this precarious balance is precisely what is necessary for adaptation, self-organization, and life to occur, and that complex systems tend to spontaneously evolve toward this “edge.”^[6]

Another fundamental feature is that complex systems consist of many (or at least several) parts that are connected via their interactions. Their components are both *distinct* and *connected*, both autonomous and to some degree mutually dependent. Complete dependence would imply order, like in a crystal where the state of one molecule determines the state of all the others. Complete independence would imply disorder, like in a gas where the state of one molecule gives you no information whatsoever about the state of the other molecules.

The components of a complex system are most commonly modeled as *agents*, i.e., individual systems that act upon their environment in response to the events they experience. Examples of agents are people, firms, animals, cells, and molecules. The number of agents in the system is in general not fixed as agents can multiply or “die.” Usually, agents are implicitly assumed to be goal-directed: their actions aim to maximize their individual “fitness,” “utility,” or “preference.” When no specific goal can be distinguished, their activity still follows a simple cause-and-effect or condition–action logic: an agent will react to a specific condition perceived in the environment by producing an appropriate action. The causal relation or rule connecting condition and action, while initially fixed for a given type of agent, can in some cases change, by learning or evolutionary variation.

The environmental conditions to which an agent reacts are normally affected by other agents’ activity. Therefore, an action by one agent will in general trigger further actions by one or more other agents, possibly setting in motion an extended chain of activity that propagates from agent to agent across the system. Such interactions are initially *local*: they start out affecting only the agents in the immediate neighborhood of the initial actor. However, their consequences are often *global*, affecting the system

of agents as a whole, like a ripple produced by a pebble that locally disturbs the surface of the water, but then widens to encompass the whole pond.

Nonlinearity

The spreading of a wave is not a complex phenomenon, though, because its propagation is perfectly regular and predictable, and its strength diminishes as its reach widens. Processes in complex systems, on the other hand, are often *nonlinear*: their effects are not proportional to their causes. When the effects are larger than the causes, we may say that there is an amplification or *positive feedback*: initially small perturbations reinforce themselves so as to become ever more intense. An example is the spread of a disease, where a single infection may eventually turn into a global pandemic. Another example is the chain reaction that leads to a nuclear explosion. When the effects are smaller than the causes, there is a dampening or *negative feedback*: perturbations are gradually suppressed, until the system returns to its equilibrium state.

Interactions with positive feedback are very *sensitive to their initial conditions*: a change in that condition may be so small that it is intrinsically undetectable, yet result in a drastically altered outcome. This is called the *butterfly effect* after the observation that, because of the nonlinearity of the system of equations governing the weather, the flapping of the wings of a butterfly in Tokyo may cause a hurricane in New York. The nonobservability of the initial perturbations means that the outcome is *in principle* unpredictable, even if the dynamics of the system were perfectly deterministic: no weather monitoring system can be so accurate that it senses all the movements of butterfly wings. This explains why weather forecasts cannot be truly reliable, especially for the longer term. Positive feedback will amplify small, random fluctuations into wild, unpredictable swings, making the overall behavior of the system chaotic. An illustration can be found in the erratic up-and-down movements of quotations on the stock exchange.

In spite of the omnipresence of fluctuations, most systems around us appear relatively stable and predictable. This is due to the presence of negative feedback, which suppresses the effects of such fluctuations. However, while negative feedback makes a system more predictable, it also makes it less controllable: if we try to change the state of such a system, we may find that our changes are counteracted, and that whatever we do the system always returns to its own “preferred” equilibrium state. Examples can be found in social systems where attempts from leaders or governments to change the behavior often are actively resisted so that they eventually come to nothing.

The dynamics of complex systems typically exhibits a combination of positive and negative feedbacks, so that certain changes are amplified and others dampened. This

makes the system’s overall behavior both unpredictable and uncontrollable. Moreover, such systems are normally open, which means that they exchange matter, energy and/or information with their wider environment. For example, an economy or ecosystem is dependent on the climate, and the amount of sunlight, rain, and heat that it produces. These in-going and out-going flows make the dynamics even more complicated, since we cannot know every external event that may affect the system. For example, a thriving economy or ecosystem may suddenly collapse because of the invasion by a foreign pest. Furthermore, the input of energy (such as sunlight) tends to feed amplification processes, so that they never reach the equilibrium that would otherwise follow the exhaustion of resources.

Modeling Complex Systems

For the above reasons, traditional deterministic models (such as systems of partial differential equations) of truly complex systems are in general impracticable,^[10] if not in principle uncomputable.^[11] In nonlinear systems, simplifying the model by using approximations is dangerous as well. The common way to approximate the effect of complex interactions by reducing it to the “mean field” (i.e., the average effect of many discrete actions performed by independent agents) can actually lead to fundamental errors. For example, a differential equation representing the “mean field” effect may predict that a certain perturbation will die out because it is too small, while a computer simulation of the individual agents finds that its effect is amplified by positive feedback until it dominates the system.^[12]

Because of these intrinsic difficulties with mathematical models, complexity researchers typically prefer computer simulations, which, while of course being approximations as well, are easier to manipulate, so that more different factors and variations of the model can be explored. Here, the system’s evolution is traced step-by-step by iteratively applying the rules that govern the agents’ interactions, thus generating the subsequent states of the system. Such simulations typically include a generator of random variations, to represent the effect of unpredictable perturbations. A typical setting is inspired by the Darwinian mechanism of natural selection, in which the rules that determine an agent’s behavior are randomly “mutated” and sometimes recombined with the rules of another agent, after which the “fittest” or best performing agents or rules are selected to carry on, while the others are eliminated. To explore the possible behaviors of the system, many different “runs”—with different initial conditions or random variations during the process—of the simulation are performed. The main variable values for each run are collected. These results are then analyzed statistically to discover recurring trends.

This sometimes produces very robust results, in the sense that all runs, however different in their initial

behavior, eventually appear to converge to the same type of stable pattern. In the majority of cases, the outcomes can be classified into a relatively small number of distinct categories. This provides the researchers with a qualitative picture of the most likely results—and hopefully an insight into the factors that promote one outcome rather than another one. It is only exceptionally that no clear pattern can be discerned in the outcomes of the different simulation runs. The reason that complex systems in spite of their intrinsic unpredictability tend to settle into a relatively small set of recognizable behaviors is their inherent tendency to *self-organize*.

SELF-ORGANIZATION

Self-organization can be defined as the spontaneous emergence of global structure out of local interactions. “Spontaneous” means that no internal or external agent is in control of the process: for a large enough system, any individual agent can be eliminated or replaced without damaging the resulting structure. The process is truly *collective*, i.e., *parallel* and *distributed* over all the agents. This makes the resulting organization intrinsically *robust* and resistant to damage and perturbations.

As noted, the components or agents of a complex system initially interact only locally, i.e., with their immediate neighbors. The actions of remote agents are initially independent of each other: there is no correlation between the activity in one region and the activity in another one. However, because all components are directly or indirectly connected, changes propagate so that faraway regions eventually are influenced by what happens here and now. Because of the complex interplay of positive and negative feedbacks, this remote influence is very difficult to predict and may initially appear chaotic.

To explain the appearance of organization, we need to make one further assumption, namely that the outcome of interactions is not arbitrary, but exhibits a “preference” for certain situations over others. The principle is analogous to *natural selection*: certain configurations are intrinsically “fitter” than others, and therefore will be preferentially retained and/or multiplied during the system’s evolution. When the agents are goal-directed, the origin of this preference is obvious: an agent will prefer an outcome that brings it closer to its goals. For example, in a market a firm will prefer the outcome that brings it more profit. In an ecosystem, an animal will prefer an outcome that brings it more food or that reduces its risk of being attacked by a predator. But even inanimate, physical objects, such as molecules or stones, have an in-built “preference,” namely for the state that minimizes their potential energy. Thus, a stone “prefers” the stable state at the foot of a hill to an unstable state on the top. Here, “preference” simply means that the unstable state will sooner or later be abandoned, while the stable one will be retained.

Coevolution and Synergy

Given such a preference, it is clear why an individual agent tends to “organize” itself so as to settle down in its preferred situation. The problem is that what is best for one agent is in general not best for the other agents. For example, more profit for a firm generally means less profit for its competitors, and an animal safe from attack by a predator means a predator that goes hungry. However, interaction is in general not a *zero-sum game*: a gain by one party does not necessarily imply an equivalent loss by the other party. In most cases, an outcome is possible in which both parties to some degree gain. For example, a firm may increase its profits by developing a more efficient technology, which it then licenses to its competitors, so that they too become more productive. In that case, we may say that the interaction exhibits *synergy*: the outcome is positive for all parties; all involved agents “prefer” the outcome to the situation without the interaction.

In general, such a collective solution is still a compromise, in the sense that not all agents can maximally realize their preferences. Not all the stones can end up in the same, lowest spot at the bottom of the hill, but they can all end up much lower than they were, by reducing the irregular hill to an even plain. Such a compromise reduces the tension or “conflict” between competing agents. (Such conflict would otherwise lead to instability as every action of the one triggers a counteraction by the other.) In that sense, we may say that the agents have *mutually adapted*; they have *coordinated* their actions so as to minimize friction and maximize synergy.

The achievement of this stable, synergetic state is in general a process of trial-and-error or variation-and-selection. Because agents are independent and interact locally, and because the dynamics of the system is unpredictable, they in general do not know what the effect of their actions on the other agents will be. They can only try out actions because they appear plausible, or even choose them at random, and note which ones bring them closer to their goals. Those actions can then be maintained or repeated, while the others are abandoned. This is the fundamental dynamics of natural selection. The main difference with traditional Darwinian evolution is that trial-and-error happens simultaneously on different sides: the agents *coevolve*, the one adapting to the other, until they mutually “fit.”

From Local to Global Organization

To shift from local coordination to global organization, we just need to note that all interactions between all agents in the complex system will tend toward such a coherent, stable state, until they are all mutually adapted. This process generally accelerates because of a positive feedback. The reason is that if two or more agents have reached a mutually fit state, this defines a stable assembly to which

other agents can now adapt, by trying to “fit” into the assembly as well. The larger the assembly, the more “niches” it has in which other agents can fit. The more agents join the assembly, the larger it becomes, and the more niches it provides for even more agents to join. Thus, the assembly may grow exponentially until it encompasses the global system.

This growth is typically faster when the agents are identical (e.g., molecules of the same substance) or similar (e.g., individuals from the same species), because the solution found by one agent will then suit the other agents as well, so that minimal further trial-and-error is needed once a good arrangement is locally found. This typically happens in processes of physical self-organization, such as crystallization, magnetization, or the emergence of coherent light in a laser.^[5] When the agents are all different (e.g., species in an ecosystem), each in turn needs to explore in order to find its unique niche in an environment that continues to evolve, resulting in a much less explosive development.

In the case of identical agents, the global structure that emerges is typically uniform or regular, because the arrangement that is optimal for one agent is also the one optimal for the other agents. As a result, they all tend to settle into the same configuration. An example is a crystal, where all molecules are arranged at regular intervals and in the same orientation. In this case, self-organization produces a perfectly ordered pattern. In cases where the agents are diverse, like in an ecosystem or a market, the resulting structure is much more complex and unpredictable.

Global Dynamics

If we now consider the system as a whole—rather than the agents individually—we may note that the system too undergoes a process of variation. This can be seen as an exploration by the system of different regions of its state space, thus following an intricate trajectory. (The state space of the system is merely the Cartesian product of the state spaces of all its components.) Self-organization then means that the system reaches an *attractor*, i.e., a part of the state space that it can enter but not leave. In that sense, an attractor is a region “preferred” by the global dynamics: states surrounding the attractor (the attractor *basin*) are unstable and will eventually be left and replaced by states inside the attractor.

A nonlinear system has in general a multitude of attractors, each corresponding to a particular self-organized configuration. If the system starts out in a basin state, it will necessarily end up in the corresponding attractor, so that the long-term behavior can in principle be predicted (assuming we know what the attractor is, which is generally not the case). However, if it starts out in a state in between basins, it still has a “choice” about which basin and therefore which attractor it ends up in,

and this will depend on unpredictable fluctuations. An attractor generally does not consist of a single state, but of a subspace of states in between which the system continues to move. The self-organized configuration, while more stable than the configuration before self-organization, is therefore in general not static but full of ongoing activity.

Self-organization can be accelerated by augmenting the initial variation that makes the system explore its state space: the more different states it visits, the sooner it will reach a state that belongs to an attractor. The simplest way to increase such variation is to subject the system to random perturbations, i.e., “noise.” For example, if you shake a pot filled with beans, the beans will explore a variety of configurations, while tending to settle into the one that is most stable, i.e., where the beans are packed most densely near the bottom of the pot. Thus, shaking will normally reduce the volume taken in by the beans. This principle was called “order from noise” by the cyberneticist von Foerster^[4] and “order through fluctuations” by the thermodynamicist Prigogine.^[1]

Emergence

The pattern formed by the stabilized interactions, mutual “fittings,” or “bonds” between the agents determines a purposeful or functional structure. Its function is to minimize friction between the agents, and thus maximize their collective “fitness,” “preference,” or “utility.” Therefore, we may call the resulting pattern “organization”: the agents are organized or coordinated in their actions so as to maximize their synergy.^[5] However, such organization by definition imposes a *constraint* on the agents: they have lost the freedom to visit states outside the attractor, i.e., states with a lower fitness or higher friction. They have to obey new “rules,” determining which actions are allowed, and which are not. They have lost some of their autonomy. The resulting mutual dependency has turned the collection of initially independent agents into an organization, i.e., a cohesive whole that is more than the sum of its parts. The goal of this “superagent” is to maximize overall synergy rather than individual utility. In a sense, the agents have turned from selfish individualists into conscientious cooperators. They have become subordinated (or “enslaved” in the terminology of Haken)^[5] to the regulations of the collective.

This whole has *emergent* properties, i.e., properties that cannot be reduced to the properties of its parts. For example, a cell has the property of being alive, while the molecules that constitute it lack that property; gold has the properties of being shiny, malleable, and yellow, but these properties do not exist for individual gold atoms.^[2] Rather than the parts individually, emergent properties characterize the pattern of interactions or relations between them. They typically include global or “holistic” aspects, such as robustness, synergy, coherence, symmetry, and function.

Different attractor regimes imply different properties for the system obeying that regime. For example, a circulating convection current may rotate clockwise or counterclockwise. Since it cannot be a priori predicted which attractor the system will end up in, the emergent properties of the whole cannot be derived from the properties of its parts alone. Once the attractor regime has stabilized, the behavior of the parts is rather regulated or constrained by the properties of the higher-level whole. This is called *downward causation*. For example, the correspondence between DNA triplets and amino acids in the genetic code is not determined by the chemical properties of the molecules that constitute DNA, but by evolutionary history producing a particular mechanism for “reading” DNA triplets in living cells. A random variation of that history might well have produced a different mechanism and therefore a different code. The languages that different people speak are not determined by the neurophysiology of their brain, but by the self-organization of shared lexicons and grammatical rules within a community of communicating individuals.

While the self-organized whole is intrinsically stable, it is still flexible enough to cope with outside perturbations. These perturbations may push the system out of its attractor, but as long as the deviation is not too large, the system will automatically return to the same attractor. In the worst case, the system is pushed into a different basin but that will merely make it end up in a different attractor. In that sense, a self-organizing system is intrinsically *adaptive*: it maintains its basic organization in spite of continuing changes in its environment. As noted, perturbations may even make the system more robust, by helping it to discover a more stable organization.

COMPLEX NETWORKS

The structure emerging from self-organization can often be represented as a network. Initially, agents interact more or less randomly with whatever other agents happen to pass in their neighborhood. Because of natural selection, however, some of these interactions will be preferentially retained, because they are synergetic. Such a preferentially stabilized interaction may be called a bond, relationship, or *link*. A link couples or connects two agents, in the sense that linked agents preferentially interact with each other. The different links turn the assembly of agents into a *network*. Within the network, the agents can now be seen as *nodes* where different links come together. Perhaps the most intuitive example is a social network, which links people on the basis of friendship, trust, or collaboration. Other well-known examples are the Internet, which connects computers via communication links, and the Web, which connects documents via hyperlinks. A more abstract example is the biochemical network that connects

the molecules that react with each other within a cell in order to produce further molecules.

It is easy to define an abstract mathematical network. You just need a set N consisting of nodes n_i , and then select any subset L of links from the set of all possible connections between two nodes:

$$L = \{(n_i, n_j)\} \subset N \times N$$

However, complexity researchers have observed that “natural” (i.e., self-organized rather than artificially designed) or “complex” networks tend to exhibit a number of specific features: they are *scale-free*, *small-world*, and *clustering*. These features are defined statistically: certain configurations of links appear with a much higher probability than chance. We will here try to explain these particular link distributions from the dynamics of self-organization of a network.

Random Networks

Let us assume that we start with a collection N of independent agents (future nodes of the network) that initially interact randomly, thus creating random links. This produces a *random network*, i.e., a network where the links have been selected by chance from the set $N \times N$ of all possible connections. Random networks have been extensively studied in mathematics. They exhibit the phenomenon of *percolation*: when links between randomly chosen nodes are added one by one, larger and larger subsets of N become connected into cohesive subnetworks. When more links are added, subnetworks will become connected to each other, defining a larger connected subset. When a certain threshold is passed, all subsets become connected so that there is now just a single connected network. It is said that the network *percolates*: imagine the links as tubes and a liquid being injected into one of the nodes; when the network percolates, the liquid will spread throughout the whole system, because any node is now directly or indirectly connected to any other node by an uninterrupted path or chain of links. Whatever happens in one node of the network can now in principle propagate to every other node in the network.

Small-World Networks

The maximum length of the shortest path connecting two nodes in a connected network is called the *diameter* of the network. If the diameter is small relative to the number of nodes, the network is said to be a *small-world network*. The notion derives from the “it’s a small world” phenomenon in social networks: two people encountering each other will often find that they have one or more acquaintances in common. Studies of social networks have indicated that it is in general possible to find a short sequence

of friend-of-a-friend links connecting two people. It has been estimated that on the scale of the world as a whole, two randomly chosen individuals are unlikely to be more than six such links removed from each other (“six degrees of separation”).

Whereas random networks have the small-world property, the opposite applies to regular networks. An example of such a network is a two-dimensional lattice or grid, where each node is connected to its four direct neighbors (left-right-up-down), each of which is connected to its four neighbors, and so on. In a square grid of $100,000 \times 100,000 = 10$ billion nodes, the nodes at the opposite ends of a diagonal are 200,000 links apart. This is the diameter of the network. Compare this to the distance of a mere six links that apparently characterizes the world social network with its nearly 10 billion nodes! Regular networks, where nodes are linked according to strict, repetitive rules rather than random connections, are typically large-world networks. This means that a change in one node will normally take a very long time to propagate to the rest of the network. As a result, the network will be slow to react to perturbations or innovations.

We may conclude that complex networks are not regular. But they are not random either: their linking patterns do obey certain regularities, albeit not strictly. In fact, it has been shown that a regular network can easily be turned into a small-world network by adding a small number of randomly chosen links to the otherwise strictly constrained links.^[7] These random links by definition do not care about the “distances” within the regular grid: e.g., they may directly connect nodes that are otherwise 100,000 links apart. Such random links create “worm-holes” or “shortcuts” between otherwise remote regions, thus bringing them suddenly within easy reach. As a result, a small number of random links added to a regular network spectacularly decreases the shortest path length between nodes.

Clustering

One of the nonrandom features that characterize complex networks is *clustering*. Clustering means that when A is linked to B, and B to C, then the probability is high (or at least much higher than could be expected in a random network) that A is also linked to C. In other words, two randomly chosen connections of B have a much higher than chance probability of being connected themselves.

The origin of this can best be explained by considering social networks. Here, the clustering property can be formulated as “the friends of my friends are (likely to be) my friends.” In other words, friends tend to form a cluster or community in which everyone knows everyone. The reason is simple: when you regularly encounter your friends, you are likely to encounter their friends as well. More generally, if an agent A frequently interacts with an agent B, and B interacts with C, then the probability is high that

A will sooner or later interact with C as well. If A and B have some similarity in aims that helps them to find synergy, and the same applies to B and C, then A and C are likely to discover a synergetic relationship as well.

Scale-Free Networks

A less intuitive feature of complex networks is that their distribution of links tends to follow a *power law*.^[8] There are many nodes with few links, and few nodes with many links. More precisely, the number of nodes N with a given degree (i.e., number of links) K is proportional to a (negative) power of that degree:

$$N(K) \sim K^{-a}$$

(The values of the exponent a tend to vary between 1 and 3.) A network that obeys a power law is called *scale-free*. When $a = 1$, N is inversely proportional to K : in other words, as the number of links goes up, the number of nodes with that number of links goes down proportionally.

This property has been established empirically, by counting the number of links in various networks, such as the Web or social networks. It turns out that a few nodes have an inordinate amount of links. They function as the *hubs* of the network, the central “cross-roads” where many different connections come together. The most common nodes, on the other hand, have just a few links. This means that nodes are strongly differentiated: something that happens to a hub will have a disproportionately large influence on the rest of the network, while something that happens to an ordinary node may have little or no consequences. This has great practical implications: an innovation or perturbation that appears in a hub (e.g., a central network server, a high-visibility Web page, or a person who is known by many) may change the whole network in a short time, because it is immediately propagated far and wide. By identifying the hubs in a network, it becomes easier to manipulate its dynamics, for good or for bad. Obvious applications are the spread of computer viruses, contagious diseases, new ideas, or fashions.

Whereas clustering tends to increase distances in a network, by creating locally connected clusters that have few links outside the cluster, the presence of hubs has the opposite effect. Because hubs have a very large number of links they are likely to link into many different clusters, thus acting as shortcuts that reduce the distance between the clusters. But this also means that removing a hub may break the connections between otherwise remote regions of the network. This is a danger especially in communication networks such as the Internet, where the failure of a small number of hubs may split up the network into separate “islands” that no longer communicate with each other. Similar dangers exist in ecosystems where the disappearance of one or more key species—i.e., “hubs” on which

many other species depend—may lead to a complete breakdown of the system.

Barabasi and Albert^[8] have proposed a theoretical explanation for power-law distributions based on the mechanism of *preferential attachment*: new nodes joining the network preferentially establish links with nodes that already have a large number of links. They have shown that when the probability of linking to a node is exactly proportional to the number of links of that node the resulting network obeys a power law with $a = 3$.

For a more general scenario for the self-organization of a complex network, consider a collection of agents that initially only interact locally with those that happen to pass in their neighborhood. Some of these interactions will be stabilized into enduring links. Once they have some links, the locality principle entails that agents are more likely to forge links with the “friends of their friends” than with randomly chosen others, thus promoting clustering. But agents that already have a high number of links also have many “friends of friends” (i.e., nodes two links away) and therefore they will be more likely to develop additional links within this two-step neighborhood or cluster. The more links an agent has, the larger its neighborhood, and therefore the larger the probability that it will receive even more links from within this neighborhood. Similarly, the larger the cluster, the more likely it is to receive random links from outside, thus extending the neighborhood outwards and linking it into other clusters. This determines a positive feedback, which leads to an explosive growth in the number of links. The agents that happen to be in the center of such a quickly growing cluster will become the hubs of the network.

APPLICATION TO KNOWLEDGE NETWORKS

Having reviewed key concepts typifying complex, self-organizing systems, and networks, we will sketch some possible applications of these ideas in the area of information science. Information science focuses on the knowledge that is available in the documents that are available in libraries and databases across the world. These documents are typically produced by authors or researchers who investigate a domain, building further on the results of other authors, and publishing their results in new papers or books that refer to these used sources. This knowledge producing system can be viewed as a very complex network, formed by the researchers, the concepts they use and the publications they produce. All the “nodes” of the network are linked directly or indirectly, by relations such as citation, collaboration, or information exchange. This complex system is intrinsically self-organizing: no individual or organization is in charge, or can decide in which direction knowledge should develop. Novel, globally available knowledge emerges out of the spontaneous, local interactions between the individual agents.

By applying the concepts and methods from the domain of complexity, we may hope to better understand the development and structure of this network. We can view it as a complex, adaptive system that generates new patterns (knowledge) through the complex, nonlinear interactions between multitudes of autonomous agents (individual scientists and organizations). This system has the structure of a heterogeneous network (Fig. 1), consisting of three basic types of nodes:^[13] agents, i.e., the individuals or organizations who actively process and produce knowledge, containers, i.e., the documents, databases, or journals in which the produced knowledge is stored and made available to other agents, and concepts, i.e., the abstract elements of knowledge itself, which are typically represented as keywords.

There already exists some preliminary work on subnetworks of this encompassing network, such as collaboration networks between authors^[14] or citation networks between documents. This research has found that they possess typical features of complex networks, such as being scale-free and small-world. For example, citation

Fig. 1 heterogeneous knowledge network, containing authors, concepts, and documents.

networks typically contain a small number of hubs (“citation classics”) with very many links, while most publications only gather a few citations. Some of the most successful recent methods for information retrieval, such as the PageRank algorithm underlying the Google search engine, or the HITS method developed by Kleinberg,^[15] implicitly use this network structure to identify the “hubs” of a hypertext network.

More interesting even than the static analysis of existing networks is the modeling of their evolution. We may assume that an information network will self-organize through the propagation of information between nodes across links, creating new links and nodes in the process. For example, assume that information is transferred from paper A to researcher B. After reading the paper, B may decide to get some more information linked to paper A, e.g., by contacting A’s author, or reading some of A’s references. These in turn may refer B to other authors or papers relevant for B’s interests, and so on. Some of these additional sources may turn out to be particularly important for B’s research, inspiring B to develop a new concept, published in the form of one or more papers. This process will create links (e.g., B may start collaborating with another author, or refer in new papers to papers discovered in this way) and nodes (e.g., new papers, new concepts, new journals). Such links and nodes will tend to cluster around a small number of “hubs”—thus defining a new “community” of related authors, documents, and ideas.

The emergence of a new scientific domain is a good example of the self-organization of such a community of knowledge,^[16] where people from initially diverse backgrounds find each other around a common interest, which gradually coalesces into a new paradigm. This process could be observed by mapping the network of authors, publications and keywords in a particular domain at regular intervals (e.g., every 2–5 years), and analyzing it in terms of clustering, hubs, average distances, etc. The change of these features over time may show processes of self-organization taking place. A good theory of the self-organization of knowledge communities would propose a number of processes and parameters that allow us to predict where, when, and how such self-organization is most likely to take place. Such a theory would help us to find not only the presently most authoritative concepts, publications, or authors (hubs), but those that are likely to become so in the future. This would provide a very powerful instrument to uncover emerging trends and to direct attention and investment toward the most promising people, ideas, and information sources.

CONCLUSION

The science studying complex, self-organizing systems and networks is still in its infancy. Yet, it already provides

us with a powerful new perspective and a number of promising conceptual and modeling tools for understanding the complex phenomena that surround us, including organisms, the Internet, ecosystems, markets, and communities.

On the one hand, the complexity perspective reminds us to be modest in our aims: many phenomena in nature and society are simply too complex to be analyzed in the traditional scientific manner. Openness and nonlinearity make a complex system in principle unpredictable and uncontrollable: the tiniest internal or external perturbations can be amplified into global changes. Therefore, we will never be able to capture it in a complete and deterministic model. Still, agent-based computer simulations can help us to get an insight into the qualitative dynamics of the system, and to classify and delimit the likely scenarios for its further evolution.

On the other hand, the complexity perspective gives us new reasons for optimism: while we cannot truly control a complex system, it tends to self-organize to a state where it regulates itself. This state tends to increase the utility or fitness of the system’s active components or agents, by coordinating their interactions so as to maximize synergy. The resulting organization is distributed over all the agents and their interactions, and thus much more robust and flexible than any centralized design. Moreover, it determines a number of emergent, global properties that cannot be reduced to the properties of the individual components. By understanding the underlying mechanisms, we may be able to facilitate and stimulate such self-organization, or to drive it in one direction rather than another.

One of the most recent applications of the complexity perspective is the analysis of complex networks, such as the World Wide Web, and the nonlinear processes that generate them. This has led to the identification of common statistical features of such networks: small-world, clustering, and scale-free link distributions. These notions promise a wealth of applications in the analysis of information networks, potentially helping us with the organization, management, retrieval, and discovery of relevant knowledge within masses of ill-structured and continuously changing data.

Computer-Mediated Communication (CMC)

Michael A. Chilton

Roger McHaney

Department of Management, Kansas State University, Manhattan, Kansas, U.S.A.

Abstract

Computer-mediated communication (CMC) is a field that studies the use of computers and related technologies as a means of facilitating human communication. With the decrease in cost of computer-based systems, use as a communication and collaboration medium has increased dramatically. Applications have been developed for businesses, educational institutions, and governmental agencies to meet the demand of emerging environments, and to enhance personal use of social networks. Scholarly research in the area of CMC has mirrored this growth. This entry first provides a description of CMCs, including areas in which computers have been used to facilitate collaboration, automation, and management. The second section categorizes both synchronous and asynchronous applications of CMC conferencing and communication technology by breaking applications down between task-specific and non-task specific areas of application within interpersonal, group, and mass communication venues. The remainder of this entry explores academic research in the area of CMC.

INTRODUCTION

The term *computer-mediated communication* or CMC was developed to represent the use of computers as a means of facilitating human communication. Computer-based systems have gained momentum as a communication and collaboration medium. Computer-assisted communications takes on a greater role in society as the cost of technology declines, as the communications infrastructure grows (e.g., the World Wide Web), as the cost of face-to-face meetings increases, and as social pressure to communicate and network with others more efficiently increases. Applications have been developed for businesses, educational institutions, and governmental agencies to meet their increasing demand for networked communication capability and for personal use to enhance social networks. Scholarly research in the area of CMC has mirrored this growth. The study of the impact of computers on human communications and information flow has resulted in a large collection of practical and theoretical papers. This growth has also fueled newer research streams as the number of uses for computers as an instrument of human communications continues to increase. A scholarly journal devoted to CMC (the *Journal of Computer-Mediated Communication*) has been created.

This entry will first provide a description of CMCs, including areas in which computers have been used to facilitate collaboration, automation, and management. Next it provides a framework for classifying various types of CMC and discusses each portion of the framework in terms of both example applications and research topics.

DESCRIPTION OF CMC

CMC has been described in various ways by academics and practitioners. Although some would describe CMC as virtually all computer uses that employ a user interface or involve the manipulation of data, this description may not include data or information flow between two or more people. Thus, computer applications such as statistical analysis programs, remote-sensing systems, and financial modeling programs would fit within this concept.^[1] A narrower view holds that CMC only encompasses those applications that directly assist human communication. That the term includes the word, “mediate,” implies reliance upon a third party or entity to enhance the information flow between two or more people. This entity adds something to the communication that helps improve (or at least provides the opportunity to do so) the efficiency and/or effectiveness of information flow. The addition of elements to aid information flow is what distinguishes CMC from ordinary telephone conversations, FAX communications, and electronic broadcasts (such as “webinars,” which are unidirectional). An example of an element that a computer might provide to enhance communications is the storage and presentation of large amounts of data, which is beyond the capability of human short-term memory to store. From this perspective, CMC encompasses not just the communication itself, but the entire process by which people create and exchange information using electronic systems and the extent to which computers assist the communications by adding some element of facilitation.

CMC can further be described according to its function. CMC is utilized in such diverse areas as teaching and learning, in social networking (for both personal and professional reasons), for dissemination and/or control of information, and for entertainment of various kinds. The methods by which each of these functions are accomplished provide additional ways of classifying a particular CMC system. Systems may require synchronous communications or allow sharing of information asynchronously; systems may provide for unidirectional communications or they may allow interactive participation; systems may provide for either small or large numbers of simultaneous participants; and systems may provide elaborate interfaces in very controlled circumstances or they may allow very informal settings that utilize simple interfaces.

This entry will discuss CMC first in terms of function as described above; next, it will provide some descriptions of systems currently in use and discuss how these systems achieve these functions; finally, we will present the various categories of research both by discipline and by topical area and journal publication. This entry is not meant to be all inclusive of every system that might be classified as a CMC, but to provide a broad taxonomy of current systems such that future systems might be understood and classified using these criteria.

There are several characteristics of CMC that can be used for classification. If communications between people occurs in real time (i.e., if one person must hear what another is saying at the time it is said), this is called synchronous communications. Conversely, if the speaker leaves a message for the receiver, which can be retrieved at a later time, this is termed asynchronous communications. Whether a message is unidirectional or bidirectional also provides us with a classificatory characteristic. Directionality can be further subdivided into active and passive components depending upon whether the receiver is expected to interact with the speaker with more than just a verbal response, as by engaging in a business transaction, for example. The complexity of the system from both the designer's point of view and the user's point of view (so-called user friendliness) is another feature used to classify systems. Finally, the degree of control exercised when the system is used can also be used to classify systems. As we discuss each example, we will use these categories to describe them.

CMC scholarship covers a wide range of applications. This is due in part to the number of potential applications for this technology and in part to the number of fields it spans. The term CMC has been used to describe research in diverse areas such as from electronic messaging,^[2] office automation,^[3] distributed decision-making,^[4] electronic boardrooms,^[5] teleconferencing, informatics,^[1] computer-supported cooperative work or CSCW, decision support systems and group support systems or GDSS,^[6] and computer-assisted instruction or CAI.^[1,7]

In general, CMC systems can be broken into three distinct areas based on application. These areas are conferencing, informatics, and CAI. While each area has unique characteristics, elements common to all CMC include communication, computers, and information exchange. Rather than attempt to describe each individual area fitting within CMC, this entry concentrates on the commonalities shared by CMC applications. The first section develops a general understanding of the primary divisions within CMC by discussing conferencing and communication, informatics, and CAI.^[8] The second section categorizes both synchronous and asynchronous applications of CMC conferencing and communication technology by breaking applications down between task-specific and non-task specific areas of application in interpersonal, group, and mass communication venues. The remainder of this entry explores academic research in the area of CMC.

PRIMARY FUNCTIONS OF CMC

Teaching and Learning

CMCs are used in several distance education scenarios. Lectures can be prerecorded and broadcast to students all at once or provided on a file server to allow asynchronous use. Lectures can also be broadcast live and can allow for either active or passive audience participation. Technology is available that allows for storage of recorded lectures and for notifying students when new lecture content is available using RSS (Really Simple Syndication) feeds. Live lectures can be uni- or bidirectional so that students can either sit passively and listen, or they can respond with questions and/or supplemental content while the lecture is broadcast. Lectures such as these are not limited to a single instructor or class, but might include several instructors located in various places broadcasting to several classrooms also located in various places. For example, a class on human resources might be enriched if some or all of the lectures were broadcast from several locations throughout the world so that students can get a better taste of the international climate and cross-cultural issues. A lecturer in Chicago might teach a local class and be piped into classrooms in New York, Los Angeles, London, Capetown, and Singapore, and be joined by lecturers in each of these locations.

Classroom-assistance programs have been developed to facilitate communications between instructors and students. Initially designed to replace the teacher's grade book, systems such as Axio, Blackboard, and others have evolved into a system that allows not just (near) real-time delivery of grades, but also for content storage and delivery to enhance learning and improve efficiency. Students can electronically complete assignments and upload them to the class repository (usually hosted by a Web server),

download and view assignments and other information pertinent to the class, and communicate with each other either synchronously or asynchronously. The idea behind these systems is to free time for both students and instructors that might otherwise be devoted to administrative tasks so that the time can be used more effectively for learning.

Classroom participation programs have also been developed and are currently being studied for their effectiveness. These systems were developed to provide real-time feedback to the instructor so that changes and assessment of learning can be made while class is conducted. Students are provided with electronic devices with which they can interact with a central recording unit when prompted by the instructor. An instructor can present a question regarding material covered in the class and allow the students to enter their answer using these electronic devices. Answers can be recorded and assessed immediately so that both the instructor and the students may become aware of learning progress. The instructor can then decide whether to repeat information not well understood or continue on to additional topics for information that has been assimilated.

Computer labs and computer simulation is another method by which teachers can transfer information to students. Prewritten lab exercises can be performed by students either in a live lab or asynchronously outside of class time so that students can see and learn the topics by performing exercises designed to provide new information to the students. This type of instruction is especially suitable for software training. Computer simulations are similar to see-and-perform lab exercises, except that the student is now required to prepare a simulation environment and then let the computer perform the actual steps. Simulations are beneficial when large amounts of data must be created and analyzed in a short period of time.

Conferencing and Collaboration

A primary use of CMC has been to facilitate direct human communication through conferencing and collaboration applications. To understand the differences in these two types of applications, we can divide them into task-related and non-task related scenarios. When people meet to accomplish specific tasks, we can categorize this as collaboration. Task-related communication systems therefore imply that such systems are designed to help participants concentrate on specific goal completion with human communication as a necessary link in the process. On the other hand, when people meet to discuss agenda items for which there is no immediate result (except perhaps plans to act in the future), we can categorize this as conferencing.

Several types of computer applications have been designed to support group conferencing and collaboration. These include instant messaging, chat rooms, text messaging, blogging, wikis, GDSS systems, groupware, and audio

and video teleconferencing. Table 1 provides a framework to categorize these systems based on whether they are primarily used for conferencing or collaboration and whether they are used synchronously or asynchronously.

Many of these systems have gained widespread acceptance and use in both personal and business settings. Instant messaging, blogging, and wikis are all examples. On the other hand, systems such as GDSS have received an enormous amount of attention in the scientific literature (e.g., Nunamaker)^[9] but have largely been used in business settings.

The term group decision support systems or GDSS has been used to describe a particular area within CMC, specifically developed from the need to support organizational decision-making processes which are being implemented by more than an individual. Unlike the non-task specific CMC applications, GDSS are generally used to facilitate a particular task. As such, GDSS can be described as an interactive computer-based system used to support collective decision making. The term *group support systems* is often associated with GDSS, but focuses specifically on processes within the group. However, a GDSS may also include provisions for collaboration from outside the group and for information management.

Generally, decision makers utilize data and models within a GDSS to communicate and solve problems. However, researchers have classified a variety of applications as GDSS ranging from systems to facilitate electronic meetings to systems to support complex decision processes.^[10]

The simplistic GDSS may consist of no more than a personal computer and voting pads combination. In this arrangement questions are answered with a simple yes and no. The results are tabulated real time and the results are displayed graphically. In more complex GDSS implementations, anonymously entered data can be displayed and options such as data consolidation, statistical analysis, voting tabulation, ranking, and agenda planning exist.

Other GDSS systems have been developed to support an organizational paradigm of computing. In this view, the GDSS integrates data from corporate transaction processing systems and decision support systems and uses this information to demonstrate various outcomes.

GDSSs have been developed for use in several different environments. Among these are decision rooms, local networks, and remote networks. In the decision room scenario, a traditional conference center is equipped with computerized aids. This allows both the advantages of face-to-face communication and electronic interaction to

Table 1 Group application classifications.

	Synchronous	Asynchronous
Conferencing	Instant messaging, chat rooms, audio and video teleconferencing	Text messaging, blogging, and wikis
Collaboration	GDSS	Groupware

be enjoyed. A networked GDSS is designed to allow participants to interact remotely. Using their own computers, communication and access to data and decision support tools is enabled. Such systems allow collaborators to be located within the same building or to be geographically dispersed.

GDSS applications enjoy several benefits, among these are anonymity, extension of group memory, parallel task completion, and democratization of decision making.

Researchers report anonymity enhances group member participation by reducing inhibition.^[10] Groups working anonymously produce greater numbers of solution clarifications, critical comments, questions about solutions, and total comments. In addition, members were more likely to be critical of ideas, to ask questions about new ideas, and to clarify or add to ideas. Anonymity acts as a buffer between people, disassociating them from their comments. This reduces behavioral constraints on group members and allows them to contribute more freely to the group discussion.^[11]

The efficiency of group work is also improved by a GDSS through the structuring of team member interactions. Resulting time savings allows a greater focus on its task performance and problem solving activities.^[12] Parallel entry also provides an increase in group efficiency. Members do not need to wait for someone to finish speaking before beginning the entry of additional information.^[13]

GDSS tools can also enhance group memory. Retaining group memory has been a traditional barrier in face-to-face interaction and often results in information loss. Features of GDSSs such as electronic information capturing and display have been specifically designed to reduce information loss. A single garrulous person cannot raise his or her voice to dominate a meeting when GDSS is used. GDSS tends to democratize the process giving members the same opportunity to express their ideas through their terminal.

GDSS applications are not without shortcomings. The use of GDSS tends to reduce face-to-face interpersonal communication and increase social distances between members. In addition, the technology used to implement a GDSS can make meetings more complicated, particularly to the facilitator.

A variety of commercial products have been developed in the area of GDSS. Among these are *VisionQuest*, an electronic meeting support software supporting anonymous brainstorming, voting, allocation, and meeting documentation. Like most GDSS products, it runs in a variety of environments and requires that network software already be in place. Other tools include Autotel Information System's *Clarity* which provides a permanent record of the group's interactions; *CM/1* by Corporate Memory Systems—a graphical meeting map combining a hypertext interface with an object-oriented database to allow groups to collaborate and organize ideas during brainstorming sessions; *Group Systems V* by Ventana, an electronic

meeting software that captures anonymous text-based ideas and displays the results in a shared screen environment; and *OptionFinder* from Option Technologies, an interactive GDSS that allows each meeting participant to vote using a numeric keypad attached to a PC then collects, calculates, and graphically displays results in real time.

Newer products that can be classified as GDSS systems include IBM's Sametime, Microsoft NetMeeting, and Citrix's GoToMyPC. These systems allow users to interact via a public or private computer network using audio, video, file sharing, Web page sharing, voting, and other functions depending on the setup at each individual computer. A server is used to run the software and host the meeting. Each participant can then log into the meeting using a Web browser. Users can share their desktops and even allow another group participant to take control. This is especially helpful in which technical support is needed or in which users can utilize a common screen to share ideas, yet are geographically dispersed.

Dissemination and Control of Information

Two aspects of information sharing among people that can have separate meanings but are many times interactive because of social agendas are the dissemination of information and the control of information. Dissemination can range from *freely available* as one would find in a public library to *strictly controlled*, as might be the case for government classified documents. Information control is easier when less information is available for dissemination, but as the volume of information grows, one technique used to protect it is through selective release. To accomplish this, an organization can simply filter the available information so that only those topics considered public by the organization are disseminated. This is especially prevalent when persuasion of the information receiver is the goal, such as in marketing/sales situations, politics, and fund raising activities. It is also prevalent when protecting confidential or proprietary information, or when misleading the information receiver is the goal (e.g., Gup).^[14]

While these concepts are not new, the use of computers to store and disseminate data and information has brought with it an increased ability to disseminate voluminous amounts of data and to control what is disseminated. The Internet and the World Wide Web have proven to be a nearly universally available conduit for information sharing for which search engines have been developed so that interested researchers can find answers to just about any question that has an answer. The other half of this complex maze of information is the information providers who make both old and new information available in electronic form and post it in Web sites on the Internet. Users can easily formulate a simple query regarding an item of interest and submit it to a search engine that will return a

myriad of related Web sites that are relevant to the query. These search engines are free to the user, but for this access, the user is subjected to advertising, which is not free, thus turning the search engine into a (hugely) profitable business.

Additional methods for dissemination of information are Web logs (blogs), wikis, and other commercial Web sites, especially those devoted to news and weather and to special interest groups such as professional organizations and political action committees. Commercial Web sites are usually devoted to advertising by providing company, product, and service information, but may be transaction-enabled so that consumers can make purchases directly online. Other forms of information disseminated electronically via the World Wide Web include legal (e.g., LegalZoom.com) and medical information (e.g., WebMD.com), government information such as governmental activities and welfare benefits, and information disseminated from professional societies, religious groups, lobbyists, and political organizers and terrorist organizations.

The mediating effect of the computer is seen first in the ability to store massive amounts of information in diverse places, as in blogs, wikis, and Web sites and second in the ability to quickly search through this information and retrieve only that which is relevant to the question.

Informatics

Informatics dates back to 1957 when Karl Steinbuch published a paper that dealt with automatic information processing. Since that time it has been defined and redefined so that it is now often confused with other disciplines such as computer science and cognitive science. For the purpose of this discourse, we focus solely on the automation of information processing as it deals with CMCs. In that sense informatics can be described as the treatment of data and information by computers to present it in such a way as to be understood and used by humans. It works like this: humans determine that certain raw facts must be stored for later use and so these facts are entered into an electronic database for storage onto electronic, magnetic, or optical media. When later retrieved, the data is processed by the computer (according to preprogrammed human instructions) and is presented in usable format as information. As the science of data storage and treatment grows, so does the ability for computers to do more of the work by picking the details that must be stored, organizing them in certain ways to eliminate repetition, and to search through available data banks to obtain only that which is necessary to solve a particular problem or perform a task.

As an example, consider a patient's medical record. The care providers can enter patient data into an electronic medical record so that it can be reviewed at a later date by a doctor who might diagnose or treat a condition, but must be cognizant of a previous history, which might add to or in some way affect the outcome of current treatment. As

more information is programmed into the computer, some decisions can be made by the computer itself, such as warning the doctor of possible drug interactions. Providing just-in-time information to the care giver is a highly desirable goal because it can improve the efficiency of medical care—improve its effectiveness and reduce its cost.^[15,16] As knowledge workers extract information on the factors that lead a physician to a certain diagnosis and a course of treatment, and program this knowledge into a computer, expert systems are created that allow the less knowledgeable care giver to analyze and perform actions that were previously left to the more educated ones. The effects of this are to push more and more of care and treatment responsibilities to the lower end of the care giver spectrum such that nurses, physician's assistants, and midwives are now relied upon for care that has become "routine" but which used to require in-patient care.^[17]

Computer-Supported Cooperative Work

The study of people working together using computerized technology is the focus of computer supported cooperative (or collaborative) work or CSCW. While this area can be classified under the umbrella of CMC, the goal of researchers in this area is to develop better ways to use computer technology to further enhance the group work process. Key concerns include trying to better understand the role time and location play in the process. The focus of CSCW is the social interaction of people, not technology. Typical topics in CSCW research include e-mail, shared applications, databases, hypertext, and other technical developments that improve a participants' awareness of other users and their activities. Like CMC in general, CSCW can be divided into synchronous and asynchronous domains. The term *Groupware* is used to refer to the technology used by individuals wishing to collaborate on a project. CSCW on the other hand refers to the field that studies human use of that technology.

APPLICATION VENUES

A second way of classifying CMC is to view how applications are used in various communication venues. In general these venues are: interpersonal, group, and mass communication.

Interpersonal

CMC systems developed specifically for communication support between two individuals or within a very small group are classified as interpersonal. Interpersonal communication systems can be synchronous or asynchronous with text, audio, and video based-communication being passed between system users. Synchronous communications operate in a real-time or near real-time atmosphere.

Text-based chat, video chat, and voice communication have all been implemented using computer technologies to facilitate synchronous interpersonal communication. Asynchronous systems generally are based on stored text, audio, or video files. One of the most common asynchronous interpersonal communication systems is e-mail, but other applications are gaining popularity with video, text, and audio implementations. These applications involve digitally storing information then transmitting them to the receiver who can listen to or view the message at his/her leisure.

Text-based chat and messaging

Chat and messaging systems provide a synchronous, text-based way to communicate with people all over the world. Most real-time chat systems rely on the Internet as a transmission medium. In general terms, Internet relay chat (IRC) systems consist of various separate networks of chat servers or machines that allow users to connect. Once connected to a server, text-based communication can begin. Besides providing a means for interpersonal communication, chat systems are often used to enable communication between larger groups of people. The largest chat networks at this time are EFnet, IRCnet, QuakeNet, and Undernet. In most applications, the user will run a program called the client and connect to a server on one of the nets. The server relays information to and from other servers on the same net. Some of the best-known client programs include mIRC which runs in a windows environment, X-chat runs under Mac's OS X, and ircII which runs on Linux systems. A client connected to a chat network has the option of joining one or more channels. These channels are used to categorize and separate conversations by topics. Chat networks may have several thousand channels available at any time and the user can generally initiate a new channel. Conversations may be public (everyone in the channel will see the typed messages) or they may be private (communication is between only invited people) depending on the way in which the channel was created.

IRC chat is currently declining in use largely due to the popularity of instant messenger software systems. Providers such as Yahoo, Microsoft, and AOL all have provided software focused on allowing users connected to the Internet via computer or mobile device to send and receive text messages in real time. Additionally, other features such as webcam use, file transfers, and message storage have added to the sophistication and desirability of these applications.

Video conferencing

Interpersonal video conferencing facilitates synchronous communication using video and audio. Like many CMC tools, this communication method can save time and

reduce travel costs. Video conferencing software currently offers everything from compressed low-bandwidth images on desktop PCs with messenger software to full-motion, broadcast quality video. Frequent users may utilize private line video conferencing and less frequent users may opt for standard Internet access. Video conferencing can be either one-way or two-way interactive and provide a multimedia mix of voice and graphics in addition to video. Personal video conferencing is focused on one-on-one, person-to-person interaction. Other applications of video conferencing might be directed toward larger groups of people. One of the best-known video conferencing software packages is Polycom. Instant messenger softwares such as Yahoo!Messenger also allow video conferencing.

Voice communication

Audio conferencing programs digitize speech as the user speaks and sends the digital data over the Internet or other transmission media. Often this is called voice over IP or VOIP. In order to match sound quality comparable to regular telephone service, most audio communication applications compress sound information before transmitting. In full duplex conversations, sender and receiver can speak and hear the other person simultaneously. In half duplex applications, only one person can speak at a time.

Various commercial products have been developed to support audio CMC applications. Currently, cable television companies market Internet phones and applications such as Skype provide VOIP services for users via their computers. Messenger software also incorporates VOIP services.

The main disadvantage with VOIP communication applications is that most offer proprietary compression schemes, which make compatibility across applications difficult. Internet bottlenecks and transmission interruptions can also slow the natural cadence of communication as well.

E-mail

Electronic mail or e-mail provides a means of sending text-based messages over a communications channel. E-mail is similar to regular mail with an added advantage—speed. E-mail allows both the sender and receiver to asynchronously communicate at convenient times.

Asynchronous voice and video

Developed as an extension to e-mail software, asynchronous voice and video applications have become more popular. Digitized voice and video files are transmitted as attachments to email and viewed or heard at a time convenient to the receiver. Some messenger software allows asynchronous messages to be sent to off-line users.

Groups

CMC systems have also been developed specifically to support communication within groups. Like the interpersonal systems, group CMC has been developed to support both synchronous and asynchronous modes of communication. Text, audio, and video formats can be used to facilitate the exchange of information between system users. In terms of synchronous communication, chat systems, real-time video systems, networked meeting systems, multiple user dialog systems, and group collaboration systems have all been implemented. Asynchronous applications such as discussion boards, blogs, and electronic mailing list software have also been developed.

Chat systems

Most text-based chat systems were designed to support synchronous communication within groups. The same applications used to support interpersonal communication are also used to support groups over the Internet or other computer networks.

Real-time video

Several real-time video conferencing software packages are currently available. Some of these have been developed for use in educational settings. Of these, Polycom is one of the best known and most widely used. Polycom allows users to hold desktop video conferences using the Internet as a transmission channel.

Networked meeting software

Networked meeting software generally refers to a package which supports synchronous collaboration tools like group chats, shared whiteboards, multiuser editors, Web slide shows, or and shared applications running simultaneously on the Internet or other network. A number of these platforms have emerged in both the business and education arenas.

Multiple user dialog

A variety of multiuser environments have become available to support real-time group communication and collaboration over computer networks. Multiple User Dialogs or MUDs and related systems such as Object-Oriented MUDs or MOOs were derived from systems developed by the gaming community in the 1970s and 1980s. Many of the original MUDs have been extended to provide real-time conferencing and collaborative environments. Sometimes called text-based virtual realities, these multiuser environments can be used to facilitate group interaction. MUDs are generally text-based sites that allow people to connect to the same place at the same time. Unlike

conventional chat rooms, they allow program manipulation and interaction through supporting software. In other words, the decision of one user can impact the perceived environment of another user. Synchronous communication is usually a component of the system.

When logged onto a MUD, an individual types rather than talks, reads rather than listens, and manipulates programs to describe themselves and the current state of the virtual environment. Resulting descriptions are generally text-based and in real time.

Recent advances in Internet bandwidth and software sophistication have enabled these same concepts to be enhanced with 3-D graphics and additional features such as voice. Gaming and social software systems such as World of Warcraft (WOW) and Second Life have added avatar capability to give users an appearance and facilitate communication more closely emulating real-world interpersonal communication.

Groupware and collaboration

Groupware encompasses a wide set of technologies used to support interpersonal and group collaboration. Groupware ranges from e-mail to Electronic Meeting Systems (EMS) to workflow collaboration tools. Generally speaking, groupware provides tools to solve *collaboration-oriented* business problems. The general concept driving groupware is the intent to foster collaboration and interpersonal productivity. This is accomplished through the technical automation and enhancement of a variety of tasks. Some groupware applications seek to integrate the functionality of e-mail with other technologies such as calendar/scheduling software. Others integrate group work processes, workflows, and meetings.^[18]

Newsgroups and blogs

Unlike the related asynchronous interpersonal CMC technology, e-mail, newsgroups facilitate group asynchronous communication. Rather than receiving messages directly, newsgroup messages are posted to groups. These groups are organized into topic headings. The user can decide which topics are of interest and choose which messages to view or download. An early newsgroup system was called the Usenet. Usenet was an international forum where asynchronous discussions on myriad topics are constantly taking place. Usenet discussion was been described as liberating because of its anonymous nature. As in many applications of CMC, participants are judged on their words, rather than on outward appearance, age, or gender.

Newsgroups have declined in popularity over time until they have almost become a relic of early Internet use. Their functionality has largely been replaced with Blogs and discussion boards which provide much of the same functionality.

Electronic mailing lists

Like newsgroups, electronic mailing lists are an asynchronous group communication technology. Mailing lists use e-mail technology to disseminate information and facilitate discussion. In many mailing list systems, a user subscribes to a list. After acceptance, copies of every message sent to the group will be routed to each member on the list. If the list is moderated each message will be reviewed by a moderator prior to being disseminated to each member. Most mailing lists will have three email addresses. These are:

- The Subscription e-mail: To subscribe to the list.
- The List e-mail: To send messages to the list.
- The Administrator/Moderator e-mail: To contact the administrator or moderator of the list.

Mailing lists fall into two categories, manual and automatic. Manual lists are generally moderated or controlled by a particular person. This person accepts, rejects, or edits message contents. Automatic lists are not generally moderated. Instead computer programs called robots are used for administration. Two common robots are LIST-SERV and Majordomo. Other types of mailing lists allow readers to read messages but not send new messages.

Social networking software

Like groupware, social networking software provides communication capabilities suited to group communication situations. However, beyond group communication, social networking also allows participants to engage in individual discussions and mass communication within a shared environment. In general, social networking focuses on the construction and development of like-minded online communities and provides a variety of Web-enabled ways for users to interact. Social networking is currently used by millions of people in both work settings and in their personal lives. Some of the most common social networking sites are MySpace, Facebook, Bebo, Orkut, Second Life (a virtual 3-D social network), and Cyworld (also 3-D).

Mass

CMC systems have also been developed specifically for mass communication. This means computer systems facilitate one-to-many communication in either a synchronous or asynchronous mode.

Text

Technologies such as mailing lists, newsgroups, and Web sites have been implemented to effectively allow one-to-many communication. This is particularly true of

mediated newsgroups, Blogs, and mailing lists where a single individual is able to communicate to an audience which cannot be limited.

Audio

Systems have been developed to present real-time audio over the Internet and other networks. Users with conventional multimedia personal computers, a network connection, and the appropriate software are able to listen to real-time sound broadcasts. The term podcasts has been used as a descriptor.

Video

One-to-many video applications operate over the Internet and other networks. Multicast provides one-to-many and many-to-many network delivery services. Sometimes called video casting, vidcasts, video podcasts, video streaming has become a very important Internet application. Web sites such as YouTube and iTunes have provided infrastructure that has allowed video casting to become commonplace.

CMC RESEARCH

CMC research has been found in a multitude of disciplines including communications and journalism, library science, engineering and computer science, business, criminology and forensics, knowledge and operations management, education, psychology, including cognitive science, sociology and anthropology, law and ethics, and both human and veterinary medicine. Research is not limited to each single discipline, however, and the norm is more multidisciplinary. As examples, engineering teams with medicine to discover new ways of treating and detecting disease and communicating these techniques to both engineers and physicians; computer science may team with anthropology to discover new ways to analyze ancient texts.

The range of research is also quite broad. Research may be focused entirely on hardware improvement so that data and information can be shared much more quickly than before. (As an example, consider that a 10 GB connection that stretches across the United States is fast enough to transmit an entire 24-volume encyclopedia from Los Angeles before the first bit is received in New York.) Research is also focused on software improvements to allow organizations to do more with the hardware that they have. (In fact software development often creates a need for further hardware improvement because newer software usually requires more powerful processing than was previously available.)

As research helps humankind to improve the sharing of information and to solve intractable problems, much of the problem solving is turned over to the computer because of

its ability to store massive amounts of data and recall it quickly and to process massive numbers of calculations in a short period of time. Thus, this type of research is *auto-catalytic* in nature—bigger and more powerful machines allow us to solve more problems, and this in turn provides even more problems to solve. This germinates the need for bigger and better machines, and the cycle is repeated.

The other end of the research spectrum focuses on the user. Such questions as the perceived value of an information system, the perceived success of an installed information system, and how well a user is able to interact with a system (so-called human–computer interaction) are some of areas which have received a lot of attention.

Additional topical areas fall in between the devices and the programs and the users, and include group work and interactions, individual work, performance and productivity enhancement, software that supports social networking, religion and cross cultural issues, security, cyber and information warfare, comparisons of different communications techniques, and entertainment.

Techniques used to accomplish CMC are also studied. Most people are familiar with instant messaging, chat rooms, electronic mail, blogging, and wikis and these areas have received attention in the literature. Newer techniques include VoIP, which provides telephone service over the Internet instead of the legacy telephone circuits, text messaging and other forms of communications using cellular and satellite technology, and audio and video conferencing using tools suitable for Internet transmission. One reason that the move from the legacy telephone circuit to the Internet infrastructure gets so much attention from both researchers and practitioners is that the older telephone systems utilize a method known as circuit switching, while the Internet uses a different technique born of data communications technologies called packet switching. With circuit switching, a physical line is held during the course of a phone call; with packet switching, a communications message is divided into chunks called packets and each is sent autonomously to the receiver. The need to tie up a single physical line is eliminated with packet switching and alternate routes may be used when sending the packets. This technology brings both advantages and disadvantages and so much effort is devoted to analyzing and improving upon the technique.

Computer-Supported Cooperative Work (CSCW)

Kevin L. Mills

National Institute of Standards and Technology, Gaithersburg, Maryland, U.S.A.

Abstract

In this entry, we consider various definitions for computer-supported cooperative work (CSCW) and related terms, and we draw outlines around the large scope covered by CSCW. Subsequently, we consider the main challenges that have impeded us from realizing the great promise of CSCW and we identify some factors that could help CSCW succeed. We review the current state of practice for CSCW, along with some promising technologies. We close with our outlook for CSCW.

Few contest the claim that modern information technology, supported by computers and communications, contributes to a dramatic improvement in productivity and effectiveness among individuals engaged in a wide range of tasks. Computer-supported cooperative work (CSCW) aims to provide similar improvements for “multiple individuals working together in a conscious way in the same production process or in different but related production processes.”^[1] If achieved, this aim, which has proven elusive during the relatively few years since the term CSCW was coined in 1984, promises to multiply our productivity, perhaps by more than the square of the number of users, as compared against the productivity improvements that personal computers provide to each of us as individuals.

In this entry, we consider various definitions for CSCW and related terms, and we draw outlines around the large scope covered by CSCW. Subsequently, we consider the main challenges that have impeded us from realizing the great promise of CSCW and we identify some factors that could help CSCW succeed. We review the current state of practice for CSCW, along with some promising technologies. We close with our outlook for CSCW.

DEFINITIONS

The term CSCW first appeared in 1984 to identify an interdisciplinary workshop organized by Irene Greif and Paul Cashman at MIT in August of that year for invited researchers to consider how computers might be used more effectively to support people in their various work arrangements. A second, open workshop on CSCW followed in December 1986, attracting 300 people. Since then, an international CSCW workshop^[2] has been held every 2 years starting in 1988. Because CSCW is such a new area of investigation, one might expect significant controversy and fluidity regarding its definition and focus. Surveys of the CSCW literature support this expectation.

Most observers seem to agree that CSCW, an emerging interdisciplinary field, entails some combination of computing and social science. For example, Greif^[3] suggests that CSCW is an interdisciplinary endeavor encompassing artificial intelligence, computer science, psychology, sociology, organizational theory, and anthropology. Similarly, Paul Dourish^[4] sees CSCW as a highly diverse discipline involving psychology, sociology, anthropology, network communication, distributed systems, user-interface design, and usability. Beyond agreement on the interdisciplinary nature of CSCW, opinions vary widely about a detailed definition and an exact focus for the field.

CSCW researchers seem to adopt one of two main viewpoints. One viewpoint is technology-centric, placing an emphasis on devising ways to design computer technology to better support people working together. For example, Greif^[1] defines CSCW as a distinct and identifiable research field focused on the role of the computer in support of group work. A second viewpoint is work-centric, placing an emphasis on understanding work processes with an aim to better design computer systems so as to support group work. For example, Suchman^[5] defines CSCW as “the design of computer-based technologies with explicit concern for the socially organized practices of their intended users.” Similarly, Bannon and Schmidt^[6] believe that “CSCW should be conceived as an endeavor to understand the nature of cooperative work as a foundation to designing information systems to support the work.” In a subsequent article, Schmidt and Bannon^[7] restate their position, and identify several important questions, listed below, which they believe CSCW researchers must answer.

1. What characteristics distinguish cooperative work from individual work, and what support requirements derive from those characteristics?
2. Why do people work together, and how can computers be applied to address the requirements arising from the specific reasons?

3. How can coordination requirements arising during cooperative work be accomplished more easily using computer technology?
4. What do the identified requirements imply for the development of system architectures and services?

The main emphasis of researchers holding the work-centric viewpoint is to understand cooperative work so as to design computer systems to better support cooperative work. The main emphasis of researchers holding the technology-centric viewpoint is to design computer systems to better support the requirements of cooperative work. Further, as Mahling^[8] observes, some social scientists also work in the field of CSCW.

Typically, social scientists working in the field of CSCW aim to describe and analyze the behavior that they see as people work together: focusing purely on description, not prescription. On the other hand, work-centric and technology-centric CSCW researchers aim to create computer systems that address the requirements of cooperative work groups. As such, these researchers hope that the social scientists, through their studies, will prescribe the requirements for successful CSCW systems. To date, this expectation remains unrealized, but much energy has been expended as CSCW researchers work to understand and reconcile these different views. The outlooks suggested by Suchman and by Bannon and Schmidt indicate that some researchers are attempting to work across the gap between description and prescription. In fact, some consensus appears to be building among researchers that CSCW is fundamentally a design-oriented research area. Under this view, the main focus of CSCW should be toward the design of systems that embody a deep understanding of the nature of cooperative work, and its forms and practices. As we will outline in a bit, the current scope of cooperative work, in terms of forms and practices, proves so large that the challenge for CSCW researchers may be overwhelming. First, though, we need to provide some explanation about the many confusing terms and concepts surrounding the field of CSCW.

SELECTED TERMS

Due to its broad scope and relative youth, the field of CSCW encompasses a wide array of specific and sometimes confusing terms. In this section, we introduce and attempt to distinguish among some of the more common terms. People often use *groupware*^[9] as a catchy term to refer to CSCW. More specifically, we can think of groupware as computer software and related computer networks that enable collections of people to work cooperatively. Groupware might include application-sharing programs, videoconferencing software, software for tracking document changes, electronic-mail software, and software to support the collaborative viewing of Web pages. *Workflow*^[10] is another term

often used to refer to CSCW. Workflow deals with the specific issues surrounding movement of transactions through a set of people who must act together to complete some required work. In this sense, workflow is a more specific term than groupware; however, workflow software typically supports formal work processes, and so is often excluded from the scope of groupware, which is usually considered to be software that supports less formal forms of collaboration. *Team computing*, a term coined at Xerox PARC,^[11] refers to collaborative systems to support group meetings. In general, such meetings are envisioned to occur in face-to-face settings. More recently and more conventionally, another term, *electronic meetings*,^[12] has been used to describe group meetings enhanced through the use of computers, networks, and software. A less common term, *media spaces*,^[13] occasionally appears in discussions of CSCW. The intent of media spaces is to provide a virtual meeting space where distributed collaborators can congregate electronically, meet informally, and gain all the advantages of collaborators who work together within the same physical location.

KEY DIMENSIONS OF CSCW

As indicated in the brief discussion of definitions and selected terms, CSCW involves a broad, multidimensional scope. Here we aim to distinguish some of the important dimensions inherent in CSCW, and to clarify the essential features that must be supported by CSCW systems. Table 1 lists 10 key dimensions of the complex design space for CSCW; for each dimension the table indicates two extreme design points. One important dichotomy facing designers of CSCW technology occurs along the *time* dimension: is there a requirement to support cooperative work that occurs simultaneously (synchronously) or separately (asynchronously) or both? Another decision relates

Table 1 Ten key dimensions in the CSCW design space.

Dimension	Extreme design points
Time	Fully simultaneous vs. fully disjoint
Space	All collocated vs. fully distributed participants
Group size	Small team vs. mass audience
Interaction style	Assigned workflow vs. ad hoc
Context	Single vs. unlimited collaborations per participant
Infrastructure	Fully homogeneous vs. fully heterogeneous
Collaborator mobility	All in fixed locations vs. all mobile
Privacy	Assigned by authority vs. controlled by participant
Participant selection	Assigned by authority vs. free for all
Extensibility	None vs. all functionality defined by participants

to *space*: must the individual collaborators be physically located at the same site, such as a room or an auditorium? Of course, a more complicated requirement might also exist for multiple, physically distant, sites of collocated collaborators to be brought together virtually. A third important dimension is *group size*: must the system support a small team, a department, an enterprise, or a mass audience? A fourth dimension must consider *interaction style*: does the group require support for planned or impromptu interactions or both? A fifth dimension covers *context*: do group members participate in many distinct collaborations or do they tend to participate in only one or few? A sixth dimension relates to *infrastructure*: will the group permit the deployment of homogeneous computing platforms tailored to collaboration or must the CSCW system operate across already deployed, heterogeneous computing systems? A seventh dimension defines *collaborator mobility*: will the collaborators remain at fixed locations or will some or all of the collaborators move among locations? An eighth dimension considers the degree of *privacy*: how much information can be made available about the collaborators and who should control the release of information? A ninth dimension considers *participant selection*: must the group's participants be assigned by existing group members or by some external authority or can participants self-select or search for additional participants from a larger population? A tenth dimension covers *extensibility*: does the CSCW system define the complete functionality available to collaborators or can the collaborators extend the functionality to support changing needs? These 10 dimensions provide a rich design space through which the developers of CSCW technology must navigate. Despite such richness, CSCW researchers have been able to focus on some essential features that CSCW systems must provide.

Essential Features in CSCW Systems

Much of the CSCW research literature focuses on providing collaborators with tools to support *articulation work*:^[7] establishing and evolving organizational structure, plans and schedules, standard operating procedures, and conceptual schemes for classifying and indexing information objects. In other words, CSCW aims to support the overhead that arises when work is conducted among distributed, independent agents. Articulation work includes two important threads: construction and management of a common, shared information space and workflow management. In the past, designers of workflow systems automated written procedures as maintained by each target organization, which in all cases turned out to be a fictional, idealized version of the real work process. Now, CSCW researchers understand that most work situations entail a continuous renegotiation of task descriptions and allocations. Further, researchers understand that collaborative communication must allow for ambiguity in

the negotiation processes surrounding articulation work. To support articulation work, CSCW researchers investigate essential design features in five main areas: communication, configuration, coordination, information access, and interaction. Table 2 indicates some of the specific features encompassed by each of these areas. We discuss these features further below.

Communication

Successful negotiation on issues related to organization, planning, and control requires provision of an effective system for communication among the individuals involved. For this reason, human-to-human communication is one of the key features needed for CSCW. Previous research^[14] suggests that audio is the most important channel for successful communication. Some CSCW researchers^[15,16] have investigated the effectiveness of conference calls, or open-loop multiparty audio channels. Other researchers^[17] have shown the value of shared audio channels even when a group of workers is physically collocated. The importance of collaborating around data or documents is also well established. For this reason, a group audio channel is sometimes augmented with a separate distribution channel for sharing views of a document and for highlighting on the document. More sophisticated communication systems integrate audio and data distribution channels together with video channels to compose a form of multimedia conferencing. Whether communicating live (synchronously) or in playback mode (asynchronously), humans can benefit from such multimedia channels.

For live communication, multimedia transmissions often stream data among multiple points in some form of videoconferencing arrangement so that all parties can simultaneously see and hear each other, along with any relevant documents. Satisfactory video viewing usually requires a rate of at least 15 frames/sec. Typically, multimedia communication includes an associated audio channel that requires reasonably tight synchronization with the video, within at least 200 msec. These factors place a

Table 2 Five CSCW design areas and some key design features in each.

Design area	Key features
Communication	Asynchronous, audio, data, private, shared, structured, synchronous, text, unstructured, video
Configuration	Adaptation, composition, evolution, extension
Coordination	Access control, concurrency, consistency, delegation, scheduling, versioning
Information access	Distribution, filtering, retrieval, structure
Interaction	Attention management, awareness, context management, relationship establishment and maintenance

premium on the quality of service (QoS) provided by the underlying data transmission channels. For this reason, much of the research^[18] related to networking for CSCW has investigated techniques to provide the necessary QoS transmission characteristics. Currently, the required QoS can usually be arranged by configuring a conference topology to support multiparty communications at transmission bandwidths (typically ranging up to 2.0 Mbps) provided by H.320-compliant products. Bandwidth requirements for satisfactory multimedia conferencing vary depending upon the configuration of the devices at conference endpoints—a minimal conferencing arrangement typically requires around 300 Kbps. Unfortunately, most collaborators must use the more ubiquitous Internet, which does not provide built-in mechanisms to request and achieve specific targets for QoS. For this reason, much network research^[19] related to CSCW has focused on establishing QoS for multiparty transmissions on the Internet.

In the absence of either multimedia conferencing support or audio communication channels, successful collaboration can still be conducted through the use of text-based interaction systems, known variously as chat (instant-messaging) applications or chat rooms. Text-based chat applications can also provide private channels for a subset of collaborators to hold side conversations outside the purview of the main proceedings. As chat applications become more sophisticated, they can also provide a convenient means to distribute documents, data, and images related to a collaborative session. Beyond free-flowing text-based chat applications, CSCW researchers have developed and assessed a number of techniques for enforcing structure on the dialog and interactions associated with a collaborative session. Such systems, which include newsgroups, dialog-threading applications, and indexed electronic-mail lists, have proven useful in limited ways. Studies^[20,21] have shown that the rather fixed capabilities provided by most of these systems can sometimes impede their effectiveness as a collaboration tool.

Due to the growing role of globalization in the workplace, CSCW researchers have begun to investigate how to facilitate cross-cultural communications, which must bridge differences in natural languages and social norms. Setlock and colleagues^[22] investigated the influence of cultural differences among teams, comprising American and Chinese members who work synchronously, either face-to-face or through computers, to solve two tasks. The teams worked in English. The study compares teams, consisting of all Americans, all Chinese, and a mix of Americans and Chinese, with respect to several factors (e.g., communication style, quality of interaction, persuasion, and task performance). Yamashita and Ishida^[23] considered effects of machine translation on teams, consisting of Chinese, Japanese, and Korea members, who worked through instant-messaging software to agree on an ordering of 10 figures. The study compared working with the aid of machine-translation software against collaborating

in a common second language (English). The area of cross-cultural and cross-lingual collaboration is due for increased study.

Configuration

Whether supporting small or large groups, CSCW systems have proven difficult to setup and configure. The scope of such systems is large, covering several layers of system and application software and many points in a distributed topology, both within the network and at network end points. Though relatively few CSCW researchers^[24] have chosen to investigate these issues, we suspect that the viability of CSCW systems depends in some large measure on the ease with which collaborative sessions can be established. A number of researchers^[25–29] have investigated the difficult problems associated with: (1) extending the capabilities of CSCW systems after deployment; (2) automating adaptation to changes in available resources for transmission and display of data; (3) composing CSCW systems from a range of supporting components; and (4) evolving system components to suit the changing needs of collaborators. Research surrounding the configuration of CSCW systems has not yet received the attention it warrants. Successful adoption of CSCW technology will certainly require an ease of configuration that at least equals and tracks the ease with which desktop computer software can be configured.

Coordination

Much of the communication associated with CSCW is used to coordinate work among the disparate, independent parties engaged in a collaborative endeavor. For this reason, CSCW researchers investigate features and mechanisms to help groups coordinate their activities. A major aspect of group coordination involves scheduling, whether of people, processes, or resources. While some CSCW researchers^[30] have investigated techniques to more tightly integrate calendaring software with other aspects of collaboration, such as document distribution, situation awareness, and personnel location tracking, more of the research to date has focused on process or workflow scheduling and coordination. For example, Glance et al.^[31] investigated process-structure grammars as a means to introduce flexibility into workflow languages. Such grammars describe the relationships among documents and tasks, and use constraints to express soft dependencies, rather than the hard dependencies more often introduced with process-flow languages. Similar goals motivate related research^[32] by Paul Dourish and colleagues. Other researchers^[33] focus on mechanisms that permit coordination policies to be established and changed as collaboration unfolds. CSCW researchers should also be interested in techniques for expressing, catching, and handling exceptions during the processing of workflows.

The need for such techniques arises because to date implementing workflow procedures has proven brittle. Researchers must also take interest in the issues surrounding delegation of authority and work within a workflow. Such techniques are often used by people in day-to-day work but are usually not supported well in automated workflow systems.

Aside from coordinating direct activities among people, CSCW requires mechanisms to coordinate indirect activities as individuals asynchronously access and update shared documents, files, objects, and other resources. The needed mechanisms include: control of access and concurrency and maintenance of versioning and consistency. A number of researchers have investigated concurrency control techniques. For example, Prakash^[34] has uncovered a range of concerns that arise when providing concurrency control for concurrent editing applications. These concerns include: (1) ensuring adequate response time for shared edit operations; (2) maintaining consistency of results under simultaneous updates; (3) providing adequate capabilities for a per-user “Undo” feature; and (4) ensuring effective awareness of the activities of others engaged in editing the same files. Adopting a formal approach, Ressel and colleagues^[35] use a transformation-oriented scheme to represent and reason about concurrency and “Undo” operators, as used within group editors. In a more general look at the relevant issues, Munson^[36] and Dewan^[37] discuss the larger design space, encompassing a framework for consistency control in synchronous, shared-access applications.

Achieving effective concurrency and consistency control in information sharing applications requires two underlying foundations: access-control policies and versioning policies. Access-control policies establish the ground rules under which various users may access shared information objects. Versioning policies define the ground rules under which different versions of the same object may be combined into a single, consistent copy. In a typical desktop computer, a small set of standard access-control policies is applied to each directory and file that a user creates. Should the user need to extend access to various groups for particular objects, the access-control policies can become quite difficult to establish, understand, and verify. This is one aspect of the problem that faces designers of access-control policies for CSCW. As discussed by Keith Edwards^[38] another aspect of this difficult problem is that access-control policies must be changeable during run-time as the requirements of a collaboration change.

While most access-control policies seek to enforce consistency by limiting access to a single user at once, many collaborative activities, such as joint authoring of documents, proceed more efficiently when multiple users can access the same information simultaneously. In such cases, consistency among independent, concurrent updates becomes a key concern. In an attempt to provide an

effective system for coauthoring of documents, Rees and colleagues^[39] describe a mechanism that separates proposed changes to a shared document space from the orthogonal issues of concurrency control and repository management. Specifically, as a collaborator updates a copy of a shared document, the updates are recorded in change proposals that track information the collaborator expects to revise and that record consistency relationships that must be maintained. Once recorded, change proposals can themselves be treated as shared documents. At an appropriate point, multiple versions of shared documents can be combined and residual inconsistencies can be raised for case-by-case consideration. The area of concurrency and consistency control within multiuser distributed systems remains fertile territory for research, whether applied to CSCW or other relevant applications.

Information Access

All collaborations require access to information in two classes: subject-matter information and collaboration-support information. Subject-matter information includes the data, images, video clips, spreadsheets, and Web pages that contain content related to the subject being discussed in a collaborative session. Collaboration-support information encompasses overhead data, such as session transcripts (which can include all media types: audio, video, text, images, and interaction events) of previous discussions and agreements about plans, procedures, and schedules for the work. CSCW requires the ability to structure, retrieve, distribute, filter, and index information in both classes, whatever the media type. CSCW researchers, as well as researchers in the related fields of information management and digital libraries, work on all of these techniques.

Vannevar Bush^[40] provided one of the earliest discussions of automated structuring and retrieval of information when he outlined the possibility of the *memex*, an associative memory enabling the retrieval of information encoded on microfilm, and permitting people to construct an associative web of trails through the information. The ideas behind Bush’s *memex* foreshadowed several later developments, such as the World Wide Web, publish-subscribe tuple spaces,^[41] and globally accessible persistent storage. These later developments (discussed in subsequent sections of this entry) seem poised to provide CSCW with a tremendous increase in capabilities to structure and access information. For example, hypertext, a direct descendant of Bush’s *memex*, possesses some significant strengths exploited early on by researchers of Web-based systems for collaboration^[42–45] and later adopted in several commercial products, such as Netscape Collabra™, WebMeeting™, and eAuditorium™. Unfortunately, as discussed by Jeff Conklin,^[46] hypertext has two significant drawbacks as an information access technique. First, users often experience disorientation while navigating

through hypertext, finding it difficult to identify their current place in the information, such as their route to the current page and routes to return to previous pages. Second, users who structure information as hypertext often report a significant cognitive burden associated with creating, naming, and tracking a large number of hyperlinks. For these reasons, information structuring and access remain important research topics.

Information distribution provides one possible alternative to information retrieval. Information distribution aims to automatically promulgate relevant information to people who might be interested. Such capabilities can be very handy for disseminating information in collaborative sessions. In general, information dissemination systems require some means of description, coupled with mechanisms for matching and delivery. Information subscribers must be able to indicate the characteristics of information they would find interesting and producers must be able to indicate the essential characteristics intrinsic to the information that they create. With these characteristics properly expressed, a computer program can identify matches between subscriber needs and producer data. Once matches are made, distribution can be carried out through a messaging system.

The key issues in information distribution surround description techniques. As discussed by Thomas Malone and colleagues,^[47] semistructured messages enable computers to process automatically a much wider range of information than would be possible with free-form text messages alone. In addition, semistructured messages enable people to communicate nonroutine information, which would be impossible within the confines of rigidly structured messages. Malone points out that much of the processing that people already undertake reflects a set of semistructured messages, so even if no automated processing is anticipated, people can benefit from having an available set of semistructured message templates to help them formulate messages that contain all relevant information for particular tasks. Further, by adopting a set of semistructured message templates, automated systems could be adopted and incrementally enhanced more easily over time. Malone and colleagues also illustrate that semistructured message templates can be arranged in a type hierarchy that can then be supported with a consistent set of display-oriented editors to help people construct messages. Semistructured messages seem particularly appropriate for collaborative systems because both computers and people can create, read, interpret, and act on the same messages. Semistructured messages foreshadow the later development of the eXtensible Markup Language (XML), a means to specify computer-interpretable messages that can also be read by people.

While semistructured messages work well for text data, much of the information associated with collaborative systems exists in the form of image, video, and audio information. Such rich, but unstructured, information presents

significant problems with respect to access. The key problems revolve around indexing multimedia information so that people can access it through filters and queries. Some researchers^[48] investigate techniques that employ speech-recognition technology to create text transcripts from audio streams. Once an unstructured text database exists, additional technologies can be applied to create multiple indices that identify people, places, dates, and topics included within the data. Using this approach, an audio stream, or repository of audio streams, can be indexed for retrieval or filtering. Some researchers^[49] consider audio and video together. Video presents new challenges associated with automatically dividing video clips into scenes or segments. While the audio indexing techniques can help in this process, other techniques can also be applied. For example, if an audio-video stream comes with an associated closed-caption text stream, then information can be extracted directly using topic and subject identification techniques. Other techniques can be applied directly to the video frames in an attempt to identify scene changes. Further, some researchers^[50,51] attempt to look inside video frames to identify objects and to extract text, for example on trucks, buildings, and street signs. While analysis and indexing of multimedia streams is typically tackled off-line, some researchers^[52] are attempting to perform a rough level of filtering in real-time. The challenging problems surrounding automated indexing of multimedia data continue as targets for active research; however, progress along these lines promises to boost substantially the capabilities of CSCW systems that include video and audio conferencing.

Interaction

CSCW must include support for people-to-people interaction at a distance: maintaining awareness of the state and activities of others, managing attention and context when a collaborator becomes involved simultaneously in multiple distinct collaborative sessions, and building and maintaining relationships among people who meet infrequently, if ever. These problems might be among the most difficult that CSCW researchers must address. Still, some progress can be discerned.

An important focus of interaction research deals with awareness at a distance. In order to stimulate ad hoc discussions or to coordinate work, collaborators working in distinct locations must maintain some awareness about the availability and progress of others. This can also extend to awareness about the state of collaborators in multiple, distinct collaborative sessions. The issue is further complicated by the fact that people seem averse to allowing others to peak into their personal space or activities. In a sense, there appears to be a fine line between maintaining awareness and allowing unwanted intrusions. Hudson and Smith^[53] have considered associated tradeoffs. Several researchers^[54,55] investigate video-based techniques that

can reduce the problem of intrusiveness, while simultaneously facilitating ad hoc interactions among distributed groups. Nomura and colleagues^[56] experiment with techniques to provide peripheral awareness through shared workspaces. Others^[57–59] propose mechanisms to provide awareness within the context of application sharing and groupware systems. Some researchers^[60] even imagine that desktop computers can be used successfully for impromptu interactions. Taking a less constrained view, Tollmar and colleagues^[61] have designed and experimented with several techniques intended to enhance social awareness within the work place. Awareness in CSCW systems remains an important and fertile area for research.

Another difficult challenge for CSCW researchers involves development of techniques to effectively manage the attention of collaborators, especially when individuals may become involved in multiple, but separate, collaborative sessions at the same time. Belotti and Bly^[62] examined the problem of context management in an environment where people move among physical locations to engage in various collaborations. Fitzpatrick and her colleagues^[63] studied the problem for virtual collaborations; specifically, they investigated the issues that arose as a group of system administrators collaborated remotely with each other and with system users to identify and solve problems with the configuration of computer systems. Results from the study influenced the design of Orbit,^[64] a research system to support desktop collaboration where the user engages simultaneously in multiple collaborative contexts. Other researchers attempt to solve the problem of context management through the use of various metaphors, such as “virtual places” and “virtual spaces”^[65] and “team rooms.”^[66] Even in a physical workspace, many people find it difficult to manage multiple working contexts, as well as to manage their own time and attention. Computer systems bring the possibility for people to engage in many more activities at once. Aiding people to effectively manage these more numerous contexts remains a challenging research issue.

CSCW researchers must also address a subtler problem: how can people find appropriate collaborators and then build and maintain effective relationships without much physical contact? These issues will become increasingly important as business interactions move more and more to the digital realm, which can reduce the inconvenience, cost, and other inefficiencies associated with physical travel to face-to-face meetings. One typical problem confronting people, even within the same organization, is to find appropriate experts to answer a specific question or problem, or to apply a particular body of knowledge. For this reason, several researchers^[67–69] have investigated systems to facilitate finding knowledge and expertise through a social network. Other researchers^[70–72] have explored the use of collaborative filtering systems, which do not necessarily include information about the expertise of the participants but which can be applied on a large

scale, such as the World Wide Web (the Web). Since the Web encompasses millions of users, some researchers attempt to leverage typical behaviors among Web users to help connect them to possible collaborators without incurring additional cognitive overhead. For example, Payton and colleagues^[73] devised a novel way for people to discover potential collaborators based on comparisons among individual patterns of Web browsing, which are typically logged by a computer. After converting logs of Web accesses into graphs associated with each user, a matching program can measure similarities and differences and then bring people into contact through electronic mail. Included within this research are several mechanisms intended to protect individual privacy, a concern that might be raised by potential users when a computer system is applied to passively monitor their activities. Even in some face-to-face situations, such as large conferences or meetings, electronic systems can be used to help stimulate new collaborations. For example, Borovoy and colleagues^[74] developed “Meme Tags,” wearable devices with displays that enable conference attendees to electronically share succinct ideas or opinions. Based on the shared information, conference attendees could form into groups with similar interests. Behind the scenes, a server system monitors and collects information about tag exchanges and then reflects the information back to conference attendees in “Community Mirrors,” which are publicly visible displays that present real-time views of the unfolding dynamics within a community. Similar ideas have been used within cyberspace to permit groups of individuals with related interests to form and interact from among millions of undifferentiated participants. Usenet^[75] pioneered in 1979 by Jim Ellis, provides one of the earliest examples. Usenet enables the creation of newsgroups focused on particular topics. Individual users can discover the existence of such groups, subscribe to those of interest, and then participate in asynchronous conversations through threaded, text postings. The more popular newsgroups sustain interactions among hundreds or thousands of users. Newsgroups continued in popularity as tens of millions of users moved onto the Internet during the 1990s. In fact, newsgroups have helped to form the ocean of Internet users into smaller collections of folks with similar interests. From these smaller collections, some individuals form and sustain deeper connections, a human art which can require additional assistance in the digital domain.

Establishing, developing, and maintaining human relationships typically relies on:^[13] (1) informal social contact; (2) chance encounters in hallways; (3) chats before and after formal meetings; (4) discovery of shared interests; (5) feelings of community; and (6) implicit knowledge of the state of others. While many of these factors occur naturally among collocated people, some researchers^[76] have observed that social responsibility and commitment appear to diminish when people do not meet face-to-face.

For this reason, CSCW researchers often attempt to recreate these relationship-building factors when people must interact at a distance. We have surveyed much of the relevant research already. A few CSCW researchers^[77,78] have focused specifically on building relationships with significant depth and trust while working at a distance. Research surrounding these topics will increase in importance as work becomes more reliant on digital interaction at a distance.

CSCW CHALLENGES

To derive the greatest benefit from CSCW, the supporting technology must infiltrate as widely as possible throughout the populace. CSCW researchers have conducted studies that support this assertion. For example, Steve Whittaker,^[79] in a study of users of Lotus Notes, a technology intended to support asynchronous collaboration, found that both conversations and the creation of group archives proved more successful with large numbers of diverse participants, as compared against small, more homogeneous, project teams. Similarly, Whittaker reports that a large database of material was more likely to be used and extended than a small database. Further, the presence of a moderator was found to inhibit rather than enhance discussions. In other words, Whittaker's study suggests that the larger and more diverse the population of participants and the more free-flowing the conversations, the more effective the results.

What factors inhibit the widespread adoption of CSCW technology? First, CSCW technology generally relies on a big stack of computer and network technology, operating systems and protocols, data formats and user-interface devices. The dissemination of such capabilities, while growing at a rapid pace, is far from ubiquitous, and even where these technologies have penetrated, the systems, protocols, formats, and software is far from homogeneous. We can safely observe that the telephone handset appears to be ubiquitous, while the networked desktop computer is far less so. Some progress can be discerned regarding de facto standardization of desktop computer systems and software, as well as the adoption of standards associated with the World Wide Web. Even so, these technical underpinnings on which CSCW depends continue to evolve. Further, there exists little penetration of the systems, and associated networking QoS required, to support effective videoconferencing. These facts suggest that to some large degree the pace of progress in CSCW depends upon, and must be tied directly to, those supporting technologies that achieve near ubiquitous adoption. On the other hand, as selected technologies evolve over time to become ubiquitous, the degrees of freedom available to CSCW researchers and designers also diminish.

Even assuming that the necessary networking and computing technologies achieve complete penetration throughout society, the deployment of CSCW may still be retarded by

various administrative and policy decisions, which paradoxically may in part be taken in reaction to the depth of penetration of the technologies themselves. For example, as more people gain access to the Internet the potential increases for various unwanted intrusions, eavesdropping, information theft, and denial-of-service attacks. To limit the effects of such incursions, network managers have deployed security firewalls. Such firewalls are typically configured to impede the free flow of communication among nodes on the Internet. These restrictions attempt to turn a physically ubiquitous system of nodes into logically partitioned and protected enclaves of nodes, and thus interfere with the ability of people to collaborate—especially when the potential collaborators exist within separate administrative domains.

Beyond the need for widespread adoption of the necessary underlying technology, CSCW can suffer from Grudin's inequality,^[20] which states: those who devote the time and effort to capture and record the articulation work associated with collaboration, may not be the ones who benefit most from the results. This same issue appears again, but on a larger scale associated with knowledge management, in a panel discussion held at the 1998 conference on CSCW, where participants considered the question: "can an organization shape its culture so that people will network and share expertise, making knowledge explicit whenever possible, rather than just whenever convenient?" In this case, an entire organization stands to benefit from the time invested by its individual members, while the members themselves might not gain directly from the time they invest.

Another impediment to progress in CSCW concerns a general inability to measure progress within the field. In hardware-related fields progress can be measured easily along many relevant dimensions, such as component density, execution speed, power consumption, and heat dissipation. To date progress in software-related fields has proven less amenable to quantification. A compounding factor, identified by Whittaker,^[79] is that user perceptions about the effectiveness of CSCW technology often do not match the effectiveness as measured by an unbiased, outside observer. This finding implies that measuring progress in the field of CSCW cannot rely solely on surveying the experiences of users. For this reason, large companies often spend substantial resources to set up human-factors laboratories where users can be observed and recorded while using specific technologies and where the observations and recordings can be studied to glean information about the effectiveness and efficiency of various software features. Understandably, because CSCW encompasses a complex and multifaceted research domain, measuring progress will remain difficult. Some researchers^[80] have proposed a framework intended to encompass the important dimensions along which progress can be measured, and have provided some examples^[81,82] showing how to apply the framework.

While conducting research and measuring progress in CSCW appears challenging enough, we must also consider the fact that the underlying technology on which CSCW builds continues to change at an alarming rate. Because CSCW builds on a wide range of software and networking technologies, significant advances in those fields can challenge the assumptions on which CSCW applications are constructed. In fact, CSCW applications live at the end of a long food chain of technologies, and so must adapt to any changes that arise. Further, several technologies within the food chain can change simultaneously, making it difficult for CSCW researchers and developers to track and understand the significance of the changes, let alone adapt to them. Even if CSCW researchers could adapt fast enough to technological changes, there still remains the problem of understanding and evaluating the effectiveness of the adaptations. By the time researchers gain an understanding, the underlying technologies have typically moved on again. This cycle poses quite a challenge to CSCW. Even worse, the adoption of new technologies and CSCW applications by people and organizations inevitably leads to changes in the way people work, as well as in the assumptions that people make about what should be possible or expected from CSCW in any given circumstance. For example, Olson and Teasley^[76] discuss how working arrangements among a team changed to become more loosely coupled when the team was forced to work virtually at a distance. Similarly, Malone^[83] predicts a shift in the organizational structure of corporations as they come to depend on computer-mediated coordination technologies. This coevolution between CSCW technology and the reaction of people and organizations to the technology appears even more challenging when we consider the fact that evolution along each dimension operates on different timescales. While technology evolves quickly, people and organizations tend to resist change, or to change fairly slowly, perhaps even at a generational pace. This mismatch in the pace of change adds to the difficulty CSCW researchers face when they attempt to assess progress in the field.

CSCW SUCCESS FACTORS

Given the challenges facing the field of CSCW, can we identify some keys to success? First, success depends on the degree to which CSCW technology becomes ubiquitously deployed throughout society. This implies that CSCW researchers must target their innovations and developments to ride on underlying technologies that appear poised for widespread adoption by a substantial portion of the population. Past examples of such technologies include telephones (in 1999 the Federal Communications Commission estimated that about 94% of Americans had telephones) and televisions (Nielsen Media Research-NTI reported that sometime between

1980 and 1985, televisions penetrated 98% of U.S. households). Potential future examples include the World Wide Web, which connects millions of desktop computers together, and to information and communication services. To date, World Wide Web technology has penetrated to between 50% and 70% of the population in industrialized nations, depending on the specific country, as reported in a study, "Truly a World Wide Web: Globe Going Digital," conducted by the Pew Global Attitudes project, released in May 2006. That study reported that the percentage of Americans with online access increased from about 64% in 2002 to 70% in 2005, while Internet usage by the world's two most populous countries lags: only 38% of Chinese and 14% of Indians used the Internet in 2005. While not certain, desktop computers and the Web seem likely candidates for near ubiquitous deployment.

Second, CSCW researchers must focus their efforts to understand and account for the characteristics of cooperative work. Some researchers have already contributed in this way. For example, Ehrlich^[9] reports themes from research about group work. Communication among groups is generally ad hoc, informal, and unplanned, which implies that CSCW researchers should develop techniques that can support such interactions in the digital world. Group members also need to maintain awareness about the availability of others to communicate, and about the state of joint work, which implies that CSCW researchers should seek to improve our ability to accomplish these tasks when working through computers and across networks. Further, issues related to sharing information often hinge on subtle notions of anonymity, which suggests the CSCW researchers should continue to experiment with mechanisms to manage the release of personal information in cooperative settings. In another contribution, Schmidt and Bannon^[7] suggest some guidelines to consider when designing systems to support cooperative ensembles. Cooperative ensembles: (1) exist as large assemblies or as groups embedded within larger assemblies (which implies that CSCW researchers should focus on techniques that scale); (2) often emerge to handle a particular situation, then dissolve (which implies that CSCW researchers should explore techniques that ease the burden of establishing collaborative sessions); (3) exhibit continuously changing membership, or membership that cannot be determined (which implies the CSCW researchers should investigate techniques for finding and forming effective subsets from larger populations); and (4) often intersect (which implies that CSCW researchers should develop techniques to manage multiple collaborative contexts, including mechanisms to control the dissemination of information in accordance with policies that might conflict). MacKay^[13] highlights another key to success when she identifies the importance of mechanisms that enable people to control who can see or hear them at any time, and to know when someone is seeing or hearing them. MacKay also discusses a critical issue surrounding

interaction and interruption. Specifically, individuals desire to determine the intention of any proposed connection or interaction, and to avoid communications that might disturb their work. These observations imply that CSCW researchers could focus productively on mechanisms to automate the initiation and management of interactions.

A third key to success for CSCW relates to automated support for coordinating group activities. While CSCW researchers are now convinced that most workflow and coordination processes demand continuous negotiation among participants and entail liberal application of techniques to handle unanticipated exceptions, the work of coordination remains largely a domain where only people add value. While selected CSCW researchers investigate automated, language-based support for flexible workflow processes and for negotiation and coordination, this territory remains wide open. Will agent-based coordination systems really work effectively? Can constraint-based languages be applied to achieve flexible information and transaction flow? Can automated methods support coordination among people, or are the problems too hard? Finding the right balance between automated support and human responsibility could improve the prospects for CSCW technology to go beyond communication to include coordination.

CURRENT PRACTICE OF CSCW

While some technologies appear promising as foundations for advances in CSCW, it should prove instructive to consider the current state of the practice. The typical collaborative session today consists of a telephone conference where collaborators discuss content, which might include faxed documents or perhaps some shared electronic documents, such as presentation slides or word-processing files that might be supported by change tracking capabilities. In some advanced situations, a collaborative activity that extends beyond particular real-time sessions might also be supported by a Web site, with one person elected as the editor. Usually, files to be added to the Web site would be sent by electronic mail to the editor. This typical collaborative session leverages a ubiquitous technology, the telephone network, which also happens to provide one of the most important channels, audio, for quickly conveying information among people and for conducting the real-time interactive dialog that helps to coordinate understanding and consensus building among participants. Typical collaborative sessions might also exploit the telephone network to distribute paper documents through facsimile machines. This permits discussions to center around shared documents, but relies on the use of the audio channel to ensure that all participants focus their attention on the same locations within a document. Increasingly, electronic mail is replacing the facsimile as

a mechanism to distribute documents, and the documents usually adopt a widely available format, such as Adobe portable document format or Microsoft Word™ format, which also provides change-tracking capability, along with PowerPoint™ format for shared viewgraphs. These techniques help, particularly the change-tracking capability, which can be useful when several people wish to propose amendments to shared documents. Even in this case, either the document must be distributed serially to ensure all changes are recorded, or the collaborators are left to ponder changes independently proposed on various copies of the document. No clear advantage exists for either approach because it can be somewhat difficult to follow documents marked up with proposed changes. Notice that the use of electronic mail to distribute electronic documents still relies on the audio channel to coordinate the focus and attention of all participants during a collaborative session.

Some technologies aimed at improving the state of the practice have failed as yet to provide much help. For example, application-sharing systems exist (e.g., Microsoft's NetMeeting™) that provide a means to visually indicate focus on electronic documents, that support simultaneous markup of electronic documents among a group of users, and that also include audio and video conferencing capabilities. Yet, these systems are not in widespread use. Why? Few widely agreed standards exist. The systems prove difficult to configure and use. They require support for a level of network QoS that is not widely available. Videoconferencing systems, such as the roll-around stations and room-based systems available from PictureTel and Polycom, have failed to achieve ubiquity as well. Why? Such systems tend to be expensive; thus, they are deployed selectively and must be scheduled and shared. This limits their applicability for spontaneous collaboration. Further, such systems require specialized support for network QoS, usually provided through H.320-compliant dial-up lines. The Internet, while more widely deployed, does not provide the necessary support for guaranteed QoS. Systems (such as Lotus Notes) that support asynchronous collaboration can be used to disseminate documents and discussions and to trigger alerts when various events occur. Such systems have not achieved wide usage. Why? The litany of reasons should be familiar by now: lack of widely agreed standards; difficult to configure, deploy, and use; expensive to buy and maintain. A similar story can be told for collaboration servers, such as Collabra and TeamWare, another form of collaboration technology available today, but not widely used.

While the current state of the practice in CSCW appears rather primitive and the landscape of more advanced technical solutions appears strewn with failures, some technologies promise to better support CSCW in practice. For example, the Web, with a growing infiltration in society and an increasing base of widely agreed

technical standards, looms as a mass medium that can likely be exploited for collaborative purposes. In fact, as the Web's inventor, Tim Berners-Lee, has often observed,^[84] collaborative software development provided the original motivation behind the Web. Of course, Mr. Berners-Lee has also rued the fact that at its current state of development the Web appears to be a mass medium more suited for TV-like distribution of multimedia. Despite its current state, Mr. Berners-Lee and many other researchers^[85] and developers continue to seek mechanisms to improve the Web's support for collaboration. Great potential exists for CSCW on the Web because ubiquitous availability provides a crucial key to success.

Another significant development for CSCW appears to be the growing role of distributed, collaborative software development, as fostered by the "Open Source" movement.^[86] Of particular interest is SourceForge (<http://www.sourceforge.net>), a Web site that provides services to open-source software development projects distributed around the globe. SourceForge provides hosted projects with Web-based tools for collaborative software development, a project Web server, tools for software maintenance and bug tracking, mailing lists and discussion forums, databases and compile farms, software release services, and advertising. SourceForge users have the option to mix-and-match these tools, and are free to design and contribute tools that might enhance collaboration. As of May 2007, SourceForge hosted over 150,000 open-source development projects and more than 1.6 million registered users. These figures represent a fivefold increase over 5 years. We might conclude that SourceForge employs Web technology in a form intended to realize the original motivation cited by Mr. Berners-Lee: collaborative software development.

What can we conclude from our examination of the current state of the practice in CSCW? The successful CSCW technologies appear to share some traits: ubiquitously available, easy to understand, easy to set up and use, few administrative constraints, reasonable technical requirements, and affordable prices. The unsuccessful CSCW technologies fail with respect to one or more of these traits. The expansion of users on the Web seems likely to continue, perhaps achieving near ubiquity at some future date. Such ubiquity would provide a key foundation to improve computer-mediated collaboration at a distance. SourceForge provides an early glimpse of what might become possible. While current practice appears quite limited, growth in Internet-based communication suggests that we are living near the dawn of effective CSCW. A number of technologies seem particularly promising.

PROMISING CSCW TECHNOLOGIES

If we look a bit beyond the horizon of today's widely deployed systems, we can identify a few technologies that

exhibit significant promise with regard to CSCW. One suite of technologies might enable us to divide the general Internet up into virtual communities inside which we can securely conduct collaborative sessions, both in real-time and across time. Such technologies can replace the current firewalls, which divide the Internet up along administrative boundaries, with virtual enclaves, which might divide the Internet up, on demand, along the lines of function or context. Already elements of such technologies are commercially available. For example, Microsoft Windows ships with networking technology that enables users to form virtual private networks, which use encryption to establish confidential, virtual Internets on top of the physical Internet. Other commercial products, such as VMware and the XenServer, permit a single desktop computer to be divided into virtual operating systems, which provide multiple, separate contexts for users or to divide Web servers into segregated enclaves so that a single physical Web server can appear as multiple, logically distinct Web servers. Desktop, network, Web server—these assets form the ingredients needed to support collaborative sessions among distributed users across organizations, and the ability to "virtualize" each of these assets in order to support multiple but separate contexts already exists in the commercial market. What remains to be developed are: (1) techniques for connecting these distinct virtual assets into unified virtual enclaves, each consisting of virtual desktops, a virtual network, and virtual servers; and (2) mechanisms to quickly establish virtual enclaves and to support mobility among the virtual desktops and virtual servers. Some networking researchers^[87] have already investigated techniques for composing virtual enclaves, while other networking researchers^[88] have refined technology that can allow virtual networks to be established simply and on demand. Recent research^[89] promises to deliver on-demand allocation of optical communications paths, which should support virtual networks and provide sufficient QoS to support a wide-range of multimedia channels to support collaboration. At the forefront of current research, grid software available as part of the Globus software distribution^[90] is being developed to allow collaborators from multiple administrative domains to contribute resources into a virtual organization hidden from unauthorized members.

Above the networking and operating system layers, technologies for the Web are evolving in interesting ways that also promise to support improved CSCW. We previously mentioned the advantage of the XML for describing the syntax and content of information in a form both readable by people and interpretable by computers. XML^[91] seems likely to become the standard language for defining information objects exchanged among computers. Future evolutions of XML^[85] promise to annotate information objects with semantic tags that can enable intelligent interpretation on the part of supporting software applications. CSCW researchers and developers should be

able to build safely on this base. Early examples of what might be possible exist in the form of community-based Web sites, such as MySpace (with its 182 million users) and Facebook (which has 23 million members), and Web sites aimed at establishing and extending business networks, such as LinkedIn (11 million users).

XML does not include a means to describe the behavior associated with various objects, except in the form of references to programs that can implement services associated with the object. The ability to express behavior directly in a form that can be transferred between computers seems to have an important place in future automated systems. At present, candidates for this role include portable scripting languages, such as Python, RubyScript, TclScript, and network programming languages, such as C# and Java. Some researchers^[27] have used Java to implement Habanero, a combined synchronous-asynchronous collaborative system that shows how the power of mobile programs can be applied to bring unprecedented interoperability, function, and performance to CSCW.

While XML and Java suggest how metadata and behavior can be described for dissemination among a network of computers, other technologies promise to provide new mechanisms to accomplish the distribution. Already, industry is busy working on notification services and publish-subscribe (pub-sub) technology that will facilitate the distribution of events and notifications to all people who have an interest. These pub-sub technologies, such as Web-Services Notification and JXTA, build on research conducted by David Gelertner,^[41] who investigated the applicability of “tuple spaces” as a means for efficient, large-scale coordination among many distributed processes.

Gelertner, a creative and visionary computer scientist, also investigates^[92] techniques for organizing multimedia experiences, so-called lifestreams, into a readily accessible form. Such technology would serve admirably to enhance the ability of collaborators to locate relevant information. Earlier, we discussed other research along these lines, such as Rough’n’Ready^[48] and Informedia,^[49] when we considered the importance of access to raw multimedia recordings of collaborative sessions. While this class of research has not yet matured to the point of widespread commercial availability, CSCW developers should be poised to make effective use of the technology.

As outlined earlier, existing technology for videoconferencing has failed to achieve widespread acceptance, probably due to expense, configuration complexity, and requirements for guaranteed QoS from the network. Despite the seeming failure of this technology, some researchers continue to investigate the possibility for radical advancements in multimedia conferencing. For example, Jaron Lanier^[93] advocates tele-immersion, a technology that aims to facilitate live multimedia interaction. The goal of Lanier and colleagues is to exploit computers, sensors, display technology, and networks to enable remotely distributed collaborators to hold virtual meetings with the same degree

of quality as if they were collocated. Similarly, Rick Stephens and colleagues^[94] have developed software to integrate large numbers of multimedia devices with high-speed networking channels to provide various sizes of Access Grid, aimed at enhancing remote collaboration across administrative domains. Success along these lines would prove invaluable to enhance the power and effectiveness of CSCW.

Not to be overlooked is research intended to exploit and enhance familiar modes of interaction as a basis to support human collaboration. For example, Paul Luff and colleagues^[95] are devising techniques that enable paper to become an input device for selecting functions, and fulfilling roles now played by computer mouse devices and graphics tablets. As another example, technology for creating digital paper^[96] and thin, flexible displays^[97] promises to enable the use of paper-like devices to load and exhibit information, which could provide significant improvements over current forms of visualization, freeing mobile collaborators from reliance on bulky, expensive, power-hungry displays. Companies (such as E Ink and Universal Display Corporation) are already developing some products along these lines. More work will be required to integrate paper-based input modalities along with digital paper or flexible displays in order to provide mobile collaborators with the ability to interact conveniently while consuming little power. CSCW developers and researchers would be well advised to increase their investigation of techniques that can exploit familiar human interaction devices, such as whiteboards, walls, tape, paper pads, markers, and pens, while simultaneously crossing the boundary between the physical and digital worlds. Examples of promising lines of research include the Easy Living^[98] and Sentient Computing^[99] projects, the Mixed Reality Architecture,^[100] and Microsoft’s “Surface”^[101] interactive table. Finding effective methods to bridge the gap between people and computers promises to yield great improvement in the interaction of groups.

OUTLOOK FOR CSCW

CSCW has become a hot technology and seems likely to remain so for the foreseeable future. The information age, and related exigencies associated with increasing globalization and specialization in our modern society, impels an ongoing transformation in the organization of work. Work is becoming more information-based, relying on computers and communications, and increasingly involves the activities of teams, often across organizational boundaries and time zones. Usually, people work on multiple teams, where the team composition changes depending upon the context, subject, and business arrangements. In this demanding environment, organizations and people naturally seek to employ any technology that can help get the job done better, faster, and cheaper. These factors presage

difficult, long-term problems whose solutions hold immense potential to benefit companies, individuals, nations, and society. Today we stand only 25 years into what might be a 50-year endeavor to research, develop, deploy, and refine effective, efficient and affordable technology for CSCW. CSCW might encompass the greatest challenges facing information technology researchers and developers, but CSCW also promises to deliver the greatest benefits that computer, network, and software technologies have to offer mankind. The central question guiding the CSCW field can be stated simply. How can computing systems enhance cooperative work without unduly constraining human collaborative processes? The question has no simple answer.

Information Studies and UCLA / Getty Program in the Conservation of Ethnographic and Archaeological Materials, University of California, Los Angeles, Los Angeles, California, U.S.A.

Abstract

This entry describes the history and evolution of the field of conservation of culturally valued materials found in museum collections. Significant steps in the evolution of museum conservation in the twentieth century include the introduction of chemists to a field previously dominated by artists and craftsmen, and a redefinition to include the prevention of damage through environmental management rather than only through activities designed to restore already damaged works. Professionalization of the field coincides with the introduction of standards and codes of practice, membership organizations, and scholarly publications. A description is included of the historical development of these standards and codes, which are generally referred to as conservation ethics. A final section examines the professional emphasis on textual, graphic, and photographic documentation used to monitor conditions and practices, and the way in which conservation activities and records have moved from behind the scenes to become part of the museum information accessible to the public.

INTRODUCTION

Conservation professionals are those whose activities are devoted to the preservation of cultural heritage for the future. Since conservation is also a term applied to the protection of biodiversity, cultural heritage specialists often distinguish their field by applying the limiting phrase of “art conservation,” perhaps more accurately termed cultural conservation as the field encompasses a broad range of specialties including natural history specimens, archives, and books. This larger purview is often described using the term preservation, notably when referring to the activities used to conserve and protect archives and books. While museums are not the only employers of conservators, who may work for universities, libraries, government agencies, research institutes, and in the private sector, museums constitute an important employer because of the significance of the collections they hold. As social institutions of cultural memory and transmission, museums are involved in the interpretation, presentation, and preservation of cultural materials (or of culturally valued natural science materials and living collections), and museum conservators contribute to all of these efforts. The evolution of museum conservation is always tied to the practice of restoration, the act of returning damaged objects to an apparently unimpaired or even improved state. Restoration has a narrower focus than conservation and one that is tied to presentation value. The complete emphasis on presentation without regard for preservation or accurate interpretation has been emphatically rejected in the modern definition of conservation.

(See “Conservation and Preservation of Library and Archival Materials,” p. 1250.)

The role of the museum conservator began at the very end of the nineteenth century, however restoration practices were always conducted on valued objects. Since museums are not static and their role continues to evolve, the museum conservator has shifted emphasis by contributing to presentation, then to research and preservation, and finally to both technical and contextual interpretation of museum objects, while continuing to work in all of these areas.

It will be illustrated how museum conservators are currently contributing to public engagement with collections; however, the development of museum conservation and its access by the public were not synchronous. The period when museums hired their first conservators occurred between 1900 and 1940, with an emphasis in those early years on either ancient collections whose condition was challenged by the transfer from an archaeological to a museum climate, or paintings, which had a high monetary value and were the focus of considerable art historical investigation. Publications by this early generation did provide some access by nonspecialists to information about the field of museum conservation. However the field was more successfully promoted by world-changing events such as the emergency transport of paintings from British museums into underground railroad stations and quarry caves during World War I and II,^[1,2] and the international recovery efforts of museum and library collections following flooding of the Arno River in Florence in the 1960s. Both events, reported in the popular press,

captured public sentiment about the significance of these collections and the importance of their preservation.^[3–5]

Conservation has joined all museum functions that are witnessing a shift in public access and interpretation resulting from the use of information technology. Until recently, conservators examined and documented museum objects, and carried out procedures designed to enhance their stability and appearance, and this documentation was shared with professional colleagues. The nature of this documentation, which has been standardized and codified through professional consensus, has been revised to include didactic and even entertaining components for public access. As museums increasingly recognize the fascination with technical clues and transformative treatments and seek content for Web sites, blogs, and online community platforms, museum conservators have sought to use these tools to engage the public about the value and interpretation of objects.

HISTORY OF THE MUSEUM CONSERVATION FIELD

The terms restoration and conservation have a long and richly debated history, with philosophical underpinnings that are the subject of numerous books and articles.^[6–8]

Restoration is recognized as a longstanding undertaking encompassing repairs made to extend the serviceable life of objects and buildings and the aesthetic life of sculptures and paintings. In terms of museum objects, the origins of restoration are frequently cited as when Italian Renaissance sculptors recarved and augmented Classical stone statuary,^[9,10] and artists retouched and revarnished earlier important paintings, all to permit display.^[11] It is important to point out that artists' materials had historically been applied to significant collections of all types with a goal toward an acceptable display appearance, without a prior understanding about how such materials might behave upon aging or interaction with collections. Once the term conservation was adapted in the late nineteenth century, it was held in opposition to restoration. Paul Coremans, an analytical chemist whose early pioneering work in conservation included founding Brussels' Institute Royal du Patrimoine Artistique, considered it "essential to differentiate between conservation and restoration."^[12,13] It was recognized in the late twentieth century that these terms cannot be easily separated: "[conservation] revolves around research, the understanding and long term preservation of the materials of which the object is made, and [restoration] relates to their enhancement."^[14] As decisions are made about the steps necessary for the preservation and public access of museum objects, all of these activities are considered under the modern rubric of conservation.^[15]

The nineteenth century was something of a florescence in the founding of museums, each with workshops and

studios dedicated to the preparation and maintenance of collections for display. It was not until the beginning of the twentieth century that conservation facilities were founded. Conservation facilities in museums were distinguished by the hiring of chemists who worked alongside existing staff including craftsmen skilled in areas such as sculpture, painting, cabinetry, model making, and taxidermy.^[16,17] Even museums founded in the seventeenth century such as the Ashmolean in Oxford, England employed sculptors, watchmakers, and portrait painters to care for the collections until the 1950s, when the first conservators were hired.^[18] Activities carried out by "repairers" in 1856 at the Victoria and Albert Museum, and preparators at American museums as recently as 1976, included "duties involving the handling of museum specimens or art objects for a variety of purposes including exhibitions, research and teaching; [and to] assist the Curators in the maintenance of collections." Preparators were supervised by Senior Museum Preparators, who

perform preservation and restoration, including the cleaning of specimens for exhibition; sort, arrange, and integrate specimens or art objects into classification or storage systems; condition and install works of art; and assemble and re-file specimens or art objects, including checking material returned from loan for possible damage.^[16,19]

Museum Conservation Laboratories

The world's oldest scientific museum laboratory, no longer called a workshop or studio, is the Chemical Laboratories of the Royal Museums of Berlin, founded on April 1, 1888, and renamed in 1975 the Friedrich Rathgen Laboratory after its founder.^[20]

Rathgen's primary contributions to conservation were in the area of archaeological materials, including a publication in 1898 of *Die Konservierung von Altertumsfunden*, translated into *Preservation of Antiquities* in 1905.^[20,21] Archaeological materials were also the focus of Gustav Rosenberg (1878–1941) the first conservator at the National Museum of Denmark whose tenure extended from 1895 to 1940.^[22] An even broader emphasis on research and preservation was pursued in the Department for Scientific and Industrial Research, founded in 1919 at the British Museum, with chemist Dr. Alexander Scott at the lead.^[21,23] Dr. Scott was succeeded at the British Museum by Harold Plenderleith in 1924. Plenderleith is well known for his book *The Conservation of Antiquities and Works of Art, Treatment, Repair, and Restoration*, which was published in 1956, and represents what many consider to be the first attempt to codify a conservation approach to a broad range of museum materials. It is lauded for its emphasis on object examination, scientific methods, and the inclusion of case studies.^[24] Another

conservation pioneer is Alfred Lucas, a British analytical chemist with a strong background in forensic science, who in 1923 became a consultant to the Egyptian Department of Antiquities in Cairo, working both with excavations and with collections at the Egyptian Museum.^[25]

In the United States, the appointment of Edward W. Forbes as director of the Fogg Art Museum at Harvard in 1909 initiated an emphasis on technical examination of artists' materials that is a mainstay of modern museum conservation. Forbes also believed that the diagnosis and treatment of artworks should rely on the same rigorous academic training afforded to other fields at Harvard.^[26] Forbes' assembly of a set of over 1400 western and oriental pigments for use as reference materials remains familiar to most contemporary conservators as a model for approaching comparative analysis.^[27] Forbes' tenure at the Fogg Art Museum culminated in the creation in 1928 of the Technical Department, with George Leslie Stout as its first conservator.^[26] While Stout was an art historian by training, he hired chemistry student John Rutherford Gettens and radiography expert John Burroughs in what was in 1931 to become the Department for Conservation and Technical Research.^[26] These men are lauded with playing a "crucial role in the early professionalization of the discipline through the introduction of innovative conservation techniques and through the development of systematized methods for examination, analysis, and documentation."^[28]

The 1930s and 1940s saw the foundation of conservation laboratories in many museums, including the Louvre Museum, the Walters Art Museum, the Boston Museum of Fine Arts, and the Metropolitan Museum of Art.^[29] The emphases on thorough examination and investigation of both collections, and materials used in conservation processes, along with careful documentation of observations and activities, are critical components of a modern museum conservation approach.

While chemistry and craft persist as important aspects of responsible conservation, there is a debate between scientific and humanistic approaches to cultural preservation that continues to rage. Art historians specializing in paintings have been the most outspoken about the potential of scientific methods to overshadow aesthetic judgments necessary for the conservation process.^[30,31] This controversy extended to sculpture when the cleaning methods for Michelangelo's *David* were debated in the American press.^[33] The concerns pit the value of scientific methods against the value of changes wrought by time, function, and cultural use, overlooking the nuanced decision making that actually occurs between these positions.

A humanistic approach persists alongside science and requires that conservators consider culturally varied standards and intentions for what it means to preserve, and that they work collaboratively with artists, community members, and other stakeholders to foster communication on these issues. For example, a revised approach to the

conservation of indigenous cultural objects and human remains involves a negotiation of context and values, since conducting research and performing treatments may alter the object or its cultural meanings.^[33–36] A committee of American conservators proposed a commentary to the Guidelines for Practice, accepted in 1997, which revised decision making for the preventive care of certain cultural objects. This commentary recognizes that deterioration may be the culturally appropriate intention for some objects:

Special cultural or contextual considerations may influence preventive conservation measures taken for a specific cultural property (e.g., sacred, contemporary, conceptual). In some cases a decision to allow deterioration to occur by avoiding certain preservation practices may be appropriate. Such decisions should be made only in collaboration with appropriate individuals connected with the cultural property.^[37]

This concept has since been accepted into national and international charters governing museum work.

CONSERVATION ETHICS

The evolution of conservation from a field of artisanal skills toward a profession that integrates technical studies and scientific research resulted in the acknowledged need for standards, responsibility, and transparency. The first such standard developed in 1931 is the Charter of Athens, devoted to "the Restoration of Historic Monuments." This code of behavior was adopted by international participants to the First International Congress of Architects and Technicians of Historic Monuments, meeting in Athens. The Charter of Athens advocated for the open critical review of restoration procedures, reliance on scientific methods, and legislative measures for the prevention of damage as a first step rather than interventions to address damage. It also stressed respect for the original materials of the monument, and collaboration with relevant experts.^[38] Like the Charter of Athens, the 1964 Charter of Venice also focused on monuments and not museum collections, and this document extends preservation beyond the monument to include the site. The Venice Charter values the physical changes wrought by all periods of use, further endorses use of scientific materials and methods, and argues against falsification by promoting restorations which are harmonious but distinguishable. This charter advocates publication of conservation work.^[39]

The first set of ethical principles applicable to conservation work in the museum was drafted in 1960 by a Committee of Ethical Standards and Procedures of the International Institute for Conservation–American Group. The resulting document adopted in 1963 is known as the "Report of the Murray Pease Committee: I.I.C. American

Group Standards of Practice and Professional Relations for Conservators,” known thereafter as the Murray Pease Report. Pease, the committee chairman and a conservator at the Metropolitan Museum of Art, considered the report to outline “. . . objective procedural requirements for the proper conduct of professional work by members of I.I.C.-A.G.”^[40] By outlining sound business practices, client confidentiality, and avoidance of conflict of interest for monetary rewards, the Pease report acknowledges the role of conservators working for private clients as well as museums. Important principles introduced in the Venice Charter are incorporated into the Pease report, including not working beyond your knowledge, not modifying known qualities of the original work to be conserved, clearly documenting sample sites and condition before carrying out any sampling or treatment, and full documentation of treatment.^[40] In 1967 the I.I.C.-A.G. membership adopted a Code of Ethics proposed by the Committee of Ethical Standards, and this document along with the Murray Pease Report are the foundation documents for the Code of Ethics and Guidelines for Practice followed by professional members of the American Institute for Conservation today.^[41]

Core concepts of ethics and guidelines continue to be reviewed and updated by committee members of the American Institute for Conservation (née I.I.C.-A.G.).^[42]

Roughly every 10 years since the adoption of the Murray Pease report, the contents and language of these documents have been revisited by the American conservation community. Increased professional specialization and the founding of graduate education for conservation in the United States prompted a review of the core documents in 1977. In 1986, the concept of reversibility was challenged. The obligation to render reversible all interventions applied as part of a conservation treatment had developed as an ethical standard in opposition to past treatments, where intractable and damaging methods and materials had been used routinely in restoration. In the 1990s a more nuanced approach to reversibility was adopted, stressing the selection of materials and methods which will not themselves age poorly or result in deterioration, compromise research potential or cultural viability, or inhibit future treatment steps. So critical is this concept that it took another 10 years of debate and discussion before the AIC membership would revise their ethics and guidelines to reflect this principle.^[42]

A second fundamental change in the professional practice of conservation, also reflected in ethical codes of conduct, has been a shift from physical interventions carried out on cultural property to management of the environment surrounding the property in order to reduce risk. These two approaches are referred to as interventive conservation versus preventive (or preventative) conservation, the latter drawn from medical terminology of preventive care. The maturation of preventive conservation as an approach has been supported by the increased

emphasis on doing no harm and respecting cultural norms, as well as on a considerable body of research conducted from the 1960s to present, which proves the benefits to collections of environmental control. This significant shift in assessment and practice was incorporated into the language of the Code of Ethics and Guidelines for Practice in the 1990s. In 1994, based on the recognition that the application of ethical conduct is varied and evolutionary for different specialties within the conservation field, Commentaries to the Guidelines for Practice were proposed by an Ethics and Standard Committee of the American Institute for Conservation and were adopted by the membership.^[43]

The European Confederation of Conservator-Restorers' Organization (ECCO) was founded in Belgium in 1991 with the aim to “. . . develop and promote, on a practical, scientific and cultural level, the profession of Conservator-Restorer of Cultural Property.”^[44] The organization adopted Professional Guidelines in 2002, in which the Conservator-Restorer's role is described as contributing “. . . to the perception, appreciation and understanding of cultural heritage in respect of its environmental context and its significance and physical properties.” These Guidelines reflect current shifts in the profession by defining the Conservator-Restorer, diagnostic examination of cultural heritage, preventive conservation, conservation (direct action on cultural heritage), restoration (direct action carried out with the “. . . aim of facilitating its perception, appreciation and understanding.”), and documentation.^[45] As is the case with the American document, the ECCO Guidelines outline ethical conduct in compliance with legal and environmental principles and collegial behavior.

DOCUMENTATION AND PUBLIC ACCESS

Increasingly professional practices in the twentieth century include museum conservators sharing their work with each other and with the public. Before this stage, museum staff often kept diaries or logs about collections care activities. In chronicling conservation history at one of the earliest museums in North America, the Smithsonian Institution, the authors indicate that

archival evidence for collections care is scant until the curatorial annual reports begin in 1881. Records from the next three decades are replete with references to care of collections and exhibition including annual reports with summaries of daily activities, diaries, letters, and other documents (p. 185).^[16]

The first publicly accessible venue for routine museum conservation reporting is the museum annual report. Evidence for collections care can be found in Annual Reports authored by the Ashmolean Museum's Keeper Arthur

Evans beginning in 1896.^[18] In many other institutions including the Metropolitan Museum of Art, the Philadelphia Museum of Art, and the Brooklyn Museum, conservation staff begins reporting activities involving analysis, equipment purchases, and treatments in annual reports in the 1950s.^[46–48]

In addition to annual reports, many early museum conservation laboratories are rich repositories of correspondence from the first quarter of the twentieth century documenting exchanges about conservation challenges, methods and materials.^[49,50] This trend toward outreach and exchange provides a marked contrast to what was previously a field with jealously guarded workshop practices, undocumented, and designed to result in invisible and transformative reconstructions completed in restoration studios.^[9]

The increased professionalization of conservation has also included the development of written, graphic, and photographic documentation as standard components of museum work, as well as the development of peer reviewed journals for the publication of conservation research and practice, and organizations dedicated to professional conservation standards. Conservation documentation in the 1930s continued to take the form of diary entries, index cards, and written reports, where remarks and treatment steps were recorded, sometimes accompanied by drawing and photographs. The first professional publication in English, *Technical Studies in the Field of Fine Arts*, was published by the Fogg Art Museum at Harvard beginning in 1932.^[28] The year 1950 saw the founding in London of the International Institute for the Conservation of Museum Objects, now called the International Institute for the Conservation of Historic and Artistic Works (IIC), and this organization began publishing the journal *Studies in Conservation* in 1952.^[51,52] Beginning in 1958, countries began to form regional groups that abided by the aims and objectives of the IIC, which include excellence in professional practice in the preservation of cultural heritage and the promotion of knowledge, practice, and standards. The United Kingdom and the United States were two of the earliest regional groups of IIC, and seven other countries and regions currently maintain chapters.^[53]

The IIC-American Group had its first meeting in 1960, and this group, now known as the American Institute for Conservation of Historic and Artistic Works, meets annually and publishes the peer reviewed quarterly *Journal of the American Institute for Conservation*. In 1946, the International Council of Museums (ICOM) was founded in agreement with UNESCO, and 20 years later a Committee for Conservation was created that actively participates in triennial meetings and publications.^[54] The International Centre for the Study of the Preservation and Restoration of Cultural Property was established in Rome in 1959, and it is known by the acronym ICCROM. Focusing on both museums and monuments, it offers publications, research meetings, seminars, and training based on

interdisciplinary collaboration involving scientists, conservators, restorers, archaeologists, art historians, curators, architects, engineers, and city planners.^[55]

Perhaps the most dramatic change to the practice of conservation documentation occurred when typed, handwritten, or printed documents and film based images were superseded in the 1970s by digital technology which became the infrastructure of all museum operations.^[56,57] Many museum conservation laboratories are believed to have switched to a digital format for their text documents by the 1980s, and digital imaging followed later with best practices documents created only this year.^[58,59] The incorporation of conservation records into a museum's digital collections management database is the subject of a major initiative by the Andrew W. Mellon Foundation which in 2008 launched the Mellon Conservation Documentation Survey, encouraging participation by "all who document objects, analysis, treatments and other processes in museum, library, or archive conservation and science departments, or who use such documentation in their work."^[60] The survey results, which will be available at the end of 2008, will establish priorities for preservation through digitization of museum conservation archives, as well as explore how to take advantage of broadening access to these records by scholars and the museum public.^[61] This could result in 100 years of diaries, logs, papers, and photographs being digitized and made Web accessible to varied audiences.

While conservation documentation has not heretofore been produced for public access, and is in fact considered confidential when it refers to privately held collections, the museum-going public has had a sustained interest in conservation, evidenced by exhibitions dedicated to the exposure of fakes *The Art of the Fake: Egyptian Forgeries from the Kelsey Museum of Archaeology*, An Internet Public Library exhibition of selected Egyptian artifacts—both real and fake, *Unearthing The Truth: Egypt's Pagan And Coptic Sculpture*, Brooklyn Museum, opening February 2009, *Fake?, The Art of Deception*, British Museum, September 30, 1990, *Fakes and Forgeries*, Minneapolis Institute of Arts, July 11–September 29, 1973, to the study of technology *Gian Lorenzo Bernini: Sketches in Clay*, Fogg Art Museum, February 28, 1998, *Gifts for the Gods: Images from Egyptian Temples*, The Metropolitan Museum of Art, October 16, 2007–February 18, 2008, *Rembrandt/Not Rembrandt in the Metropolitan Museum of Art. Aspects of Connoisseurship*, October 10, 1996, and to the process of conserving works in a museum collection. *Star-Spangled banner, The Preservation Project*, National Museum of American History, 1998–present. Conservation in public institutions has experienced a shift from activities conducted behind the scenes, with records intended only for museum staff, to an activity designed for public exploration. The Smithsonian National Museum of American History created a visible laboratory behind glass walls in 1998 to permit visitors to observe the ongoing

examination and conservation of the Star Spangled Banner, the flag that inspired America's national anthem. Additional staff for this project included educational and interpretive specialists and an exhibitions curator, unusual staffing for a conservation project, and one which won awards for public relations and exhibition.^[62]

Another pioneer in this effort to make conservation public is the Lunder Conservation Center at the Smithsonian American Art Museum and National Portrait Gallery, which includes multiple laboratories with different specialties separated from the public by glass viewing walls. Elaborate didactics in front of each laboratory include videos and text panels about completed and ongoing projects. In June 2008, conservators at the Lunder Center began posting details of conservation treatments on Twitter,^[63] a free Web-based short messaging service designed for use with mobile devices.^[64]

Though no survey exists to provide a precise number, dozens of museum Web sites now feature videos, daily diaries, and blogs about conservation. A search on the Brooklyn Museum Web site produced 2020 locations with the term conservation. The Museum has a blog under the heading of "Community," to which conservators contribute along with other museum staff, and where the public is encouraged to comment and inquire about activities. Postings describe reattaching paint on a delicate nineteenth century watercolor by Frances Flora Palmer, inviting the public to look through the microscope to compare the condition of paint before and after treatment. Another set of postings show the reuniting of the portrait and mummy of a first century A.D. Roman citizen of Egypt, separated by museum conservators in 1939.^[65]

This public aspect of conservation has culminated in a Wikipedia article entitled Conservation–Restoration, with a majority of its postings added in 2008. The use of the term Restoration aligns the site with cultural heritage preservation rather than wildlife management, the subject of another Wikipedia entry entitled Conservation. The Conservation–Restoration article received minor editorial attention until 2006, since when it has been edited 445 times, with 307 of these edits occurring between October 2007 and October 2008.^[66] In April 2008, the Publications Committee of the American Institute for Conservation recognized the audience impact and outreach potential of an article in Wikipedia, and took on the project to expand the site and increase accuracy. This expansion has included the addition of sections on ethics, the history of the profession, professional specializations, training, and links to organizations and journals, bringing the field of conservation more fully into the public domain.

CONCLUSION

Conservation is a field whose professional activities are devoted to the preservation of cultural heritage for the

future. An understanding of the foci on ethical practice, documentation, balancing humanism and science, and public outreach in the field of museum conservation make sense when viewed in the context of the profession's beginnings and its historical achievements. The evolution of the field to include the introduction of science to a craft-based activity explains the need to develop standards and formalized ethical practices. As a profession that contributes to both the interpretation and preservation of tangible and intangible values in cultural objects, conservators are intimately tied to the museum function of memory transmission. Conservation records grew from an informal form of note-keeping, to an internally valuable report on museum accomplishment, to part of the story that assists the public in appreciating and understanding collections.

Controlled Vocabularies for Art, Architecture, and Material Culture

Murtha Baca

Getty Research Institute, Los Angeles, California, U.S.A.

Abstract

There are a number of controlled vocabularies that can be used for describing and enhancing access to information resources relating to art, architecture, and material culture. These data value standards are essential for the description of movable art works, built works, and objects of material culture, as well as their visual and digital surrogates. Local, collection-specific authority files for museum and visual resource collections also play a key role in describing collection materials and providing access points for a wide range of users, both internal and external to the particular organization. So-called *folksonomies*, which are the result of *social tagging*, are not true controlled vocabularies but can be useful in providing additional access points.

INTRODUCTION

The simplest way to define vocabularies is to say that they are groupings of terms or names; vocabularies are said to be *controlled* if they are limited to a particular domain or set of concepts, and to designate a preferred form for each concept, person, or entity represented. Controlled vocabularies are organized collections of words, phrases, and/or names structured to show the relationships between terms and concepts. Authority files and thesauri are types of controlled vocabularies, but a simple *picklist* (a feature that allows users to select terms from a preset list) can also be controlled. An *authority file* is a type of controlled vocabulary that serves as a source of standardized forms of names, terms, or titles. Authority files normally include references or links from variant forms (terms or names that are equivalent to the preferred term or name) to preferred forms or “headings.” For example, in the Library of Congress Name Authority File, the name form “Ovile Master” links to the preferred form “Bulgarini, Bartolomeo” for the fourteenth-century Italian artist whose hand has been variously identified with the “Master of the Ovile Madonna,” “Ugolino Lorenzetti,” and “Bartolommeo Bulgarini,” which are all considered to be variants or synonyms for the preferred name form. Authority files, originally designed to regulate usage in library catalogs, also provide additional access points, thus potentially increasing both the precision and recall of many searches. A *thesaurus* is a type of controlled vocabulary in which each entry or record is restricted to a single meaning (unlike a dictionary). It is further characterized by relationships explicitly expressed in the structure of the vocabulary. Relationships include equivalence relationships (between synonyms in a single record), hierarchical

relationships (whole/part, genus/species, and instance between records), and associative relationships (other types of relationships between records, not hierarchical). Hierarchical and associative relationships are semantic; equivalence relationships are lexical. For example, in the *Art & Architecture Thesaurus* (AAT), a “gisant” is a type of funerary sculpture (genus/species relationship); a “predella” is the decorated base of a large altarpiece (whole/part); “firedogs,” “andirons,” and “chenets” all refer to the same type of device used to support logs in a fireplace (equivalence relationship); and “arriccio” (a type of plaster used in the creation of frescoes) is conceptually rather than hierarchically related to “fresco,” a specific type of painting (associative relationship). Associative relationships can also be used to distinguish terms from one another; for example, “rhyta” are drinking vessels held over the head. In the AAT, the record for “rhyta” is linked (conceptually and electronically) to the records for “Sturzbechers” and “stirrup cups,” which are different types of vessels but, like rhyta, rest on their side when not in use. “National Gallery of Art” and “Tate Modern” as narrower terms of “art museums” are an example of an instance relationship in a thesaurus (in this case, dealing with corporate bodies such as museums and other cultural institutions).

Controlled vocabularies can be powerful tools for describing and enhancing access to collections of any kind. They can range from a simple alphabetical list of approved terms to a complex, carefully structured thesaurus, including broader and narrower concepts, related concepts, and any number of equivalent or near-equivalent terms or names denoting the same concept, as shown in the examples discussed. In information science, controlled vocabularies are often referred to as *data value standards*,

since they provide the specific terms, names, and other data values that are used to populate *data structures* or metadata schemas such as MARC (Machine-Readable Cataloging), MODS (Metadata Object Description Schema), Dublin Core, LIDO (Lightweight Information Describing Objects), EAD (Encoded Archival Description), and others.

The cataloging rules that are used to guide the way that data values are entered into data structures are often (and, for many people, confusingly) referred to as *data content standards*—*Resource Description and Access* (RDA), *Describing Objects: A Content Standard* (DACS), and *Cataloging Cultural Objects* (CCO) are examples of data content standards for bibliographic materials, archival collections, and unique cultural objects, respectively. For a chart that clearly outlines the types of data standards, with examples, see Gilliland.^[1]

CONTROLLED VOCABULARIES FOR ART AND ARCHITECTURE

In the areas of art, architecture, and material culture, there are several vocabulary tools that have been specifically designed for describing these types of collections, such as the AAT. Other vocabularies have been developed for other types of materials but can also be applied to art and architecture, such as the *Library of Congress Subject Headings* (LCSH) and the *Thesaurus for Geographic Materials* (TGM), also maintained by the Library of Congress.

Controlled vocabularies have three main uses. They can be used as sources of standard terminology for descriptive cataloging and other forms of documentation; as knowledge bases or lookup tools for discovering the meaning of a particular term or a term for a particular concept or object, or a description of a particular individual or corporate body in the case of a name authority file; and as online searching assistants that can enhance both precision and recall in querying databases that can have multiple data values representing the same concepts, objects, or persons.

EXAMPLES OF USES OF CONTROLLED VOCABULARIES

As sources of terminology for catalog records and other forms of documentation: In a catalog record for a painting in a museum's collection or an image in a photographic archive, the following database fields or metadata elements should be populated with values from appropriate controlled vocabularies: object type, creator name, materials/techniques, creation location, subject matter, and so on. See the cataloging examples provided on the

Categories for the Description of Works of Art (CDWA) website: http://www.getty.edu/research/publications/electronic_publications/cdwa/examples.html, which indicate which fields in a database record should be populated with values from a controlled vocabulary.

As knowledge bases or lookup tools: A user wishes to know what “trompe-l'oeil” means; he or she does a search in the AAT on that term (or on a right-truncated version of the term, in the event of being unsure of the exact spelling) and retrieves a record with the scope note that begins “French term meaning ‘deceive the eye,’ applied to images so realistic that they may fool the viewer into thinking that the represented objects, scenes, textures, or points of view are real rather than images.” If a controlled vocabulary has carefully constructed hierarchical relationships and scope notes, users can even find terms for concepts for which they do not know the word. In her article “Indexing and Access for Digital Libraries and the Internet: Human, Database, and Domain Factors,” Marcia J. Bates^[2] discusses the issues associated with the fact that many users are essentially trying to describe something they do not know or for which they have knowledge gaps, while indexers know what they are describing and use specific terminology in the process of purportedly providing access points for specific materials. The use of carefully structured thesauri and other vocabularies that link both specific and more generic terms, and even “right” and “wrong” (but frequently used) terms, can go a long way toward bridging the gap between indexers and end-users. For example, in the AAT, users can navigate down the Visual Works hierarchy from “sculpture” to “funerary sculpture” to “ushabti,” or they can enter a key word search for “Egyptian and tombs” on the scope notes and also find the record for “ushabti” (with eight variant spellings), the small sculptures that the ancient Egyptians buried with their dead to accompany them in the afterlife. Or a user may have come across the name “Beggartstaff Brothers” and wants to know who these artists were. A search in the *Union List of Artist Names* (ULAN) reveals that this was the pseudonym adopted by brothers-in-law William Nicholson and James Pryde (each a well-known artist in his own right) while they were collaborating in the 1890s as poster artists. The ULAN record also has links to the individual records for each artist.

As online searching assistants: An Italian searcher wishes to know if the Getty Museum has any works by the artist designated in the scholarly literature and exhibition catalogs in the Italian language as “Gherardo delle Notti.” He enters this name in the Getty search engine and retrieves works by “Gerrit van Honthorst,” the name used in non-Italian-language publications and institutions to designate this Dutch artist who was active in Italy during the first half of the seventeenth century. This is because the ULAN, with all the variant names for this artist clustered together in a single record, is being used

as an intermediary between the searcher and the resources being searched. Similarly, a user can search on “desk” and retrieve a “cartonnier” in the Getty’s collection, even though the word “desk” does not appear on the web page for that object. This is because the power of the AAT hierarchy is being used to assist the searcher who is using a more generic, nonexpert term for a very specific object. Bates^[3] discusses the power of faceted searching (made possible by faceted thesauri like the AAT) in “Speculations on Browsing, Directed Searching, and Linking in Relation to the Bradford Distribution.”

Vocabularies in the realm of art, architecture, and material culture may contain personal names (e.g., *Leonardo da Vinci*), corporate names (*Richard Meier & Partners*), object names (*squat lekythoi*), iconographic subjects (*Hercules and the Nemean Lion*), geographic names (*Luxor, Qina governorate, Upper Egypt*), proper names of built works (*Hagia Sophia*), and so on. They can take a variety of forms. *Alphabetical lists* of approved terms or names are often used in local applications to ensure consistency and accuracy. In a controlled list, all terms should be equal in specificity and should not have overlapping meanings. *Subject headings* are terms and phrases, usually arranged in an alphabetical order, that can be combined to express compound concepts (e.g., *Triptychs—Italy—Florence—Congresses*). A *taxonomy* is an orderly classification system for a defined domain, with hierarchical relationships (e.g., *Flagellation of Christ, Passion of Christ, New Testament, Bible*, in an ascending hierarchical order). A *thesaurus* is a structured vocabulary that explicitly includes the semantic relationships between and among terms and concepts. As indicated earlier, the types of relationships in a thesaurus are “equivalence” (*still life = natura morta*), “hierarchical” (a *gisant* is a type of *effigy*, which is a type of *funerary sculpture*), and “associative” (a *charterhouse* or *chartreuse* is a type of building associated with the *Carthusian* monastic order). Any one of these types of controlled vocabularies can be used as an *authority file*—that is, a vocabulary that is used to enforce consistency by providing standardized forms of names, terms, titles, and so on. Authority files not only regulate usage, but also provide additional access points for users who may be searching on nonpreferred forms of names or terms. For example, in the *Union List of Artist Names* (ULAN), “Schiavone, Andrea” is the preferred name form for a Dalmatian artist active in Italy during the sixteenth century, but searchers can also enter queries on variant forms as diverse as “Medulić, Andrija” and “Andrea Meldolla.”

“UNCONTROLLED” VOCABULARIES AND FOLKSONOMIES FOR VISUAL WORKS

The phenomenon known as *social tagging* (also referred to as *collaborative tagging*, *social classification*, *social*

indexing, *mob indexing*, and *folk categorization*) that is prevalent on image websites such as Flickr (<https://www.flickr.com/>) and museum websites such as the Brooklyn Museum (<http://www.brooklynmuseum.org/opencollection/collections/>) is the decentralized method by which individuals and groups create, manage, and share terms, names, and so on (called “tags”) to annotate and categorize digital resources in an online “social” environment. Another example of social tagging for artworks is the Public Catalog Foundation’s “Your Paintings” tagging application (<http://tagger.thepcf.org.uk/>).

A folksonomy, which is simply an assemblage of concepts represented by tags, is the result of social tagging. It should be noted that in spite of the “onomy” at the end of the word, a folksonomy is not a taxonomy, which is an orderly, structured classification that explicitly expresses the relationships, usually hierarchical, between and among the things being classified.

Social tagging and other forms of user-generated metadata such as “crowdsourcing” are a trend in online resources that is garnering considerable attention and interest. If unstructured, nonstandardized terminology created by social tagging and other forms of user-generated metadata is linked to more highly structured, standard thesauri and vocabulary tools, the potential for enhanced end-user access is significantly increased.

COLLECTION-SPECIFIC LOCAL VOCABULARIES

Many museums and other collecting institutions have learned that merely taking terms from a published controlled vocabulary such as the Library of Congress authorities, the AAT, or ICONCLASS and using them to populate descriptive records for objects in their collections is not enough. They may find that they need to supplement these sources with scholarly or other specialized terms that are out of scope for discipline-specific vocabularies, or too specific for the level of indexing supported by more general vocabularies. Or they may use nonexpert, generic, or even erroneous terms or misspellings that cannot be found in a published, standard vocabulary tool to enhance access to collections for a wide range of users. The National Gallery of Art in Washington, DC allows users to browse its collections by using controlled lists of object types and artists’ nationalities. The Getty Museum uses collection-specific thesauri of both object types and subject matter to enable users to familiarize themselves with the works in its collections, both on the Web and in the touchscreen kiosk system in its galleries. In a collection-specific thesaurus aimed at enhancing access to nonexpert users and museum visitors, a term as unscientific as “bottles and pots” can be used to lead users to more specific types of vessels with names that would be known only to experts. While this type of “folk

classification” is not legitimate for a published, standard authority such as the AAT or LCSH, it is extremely useful in a local thesaurus, where it can be linked to the more accurate expert terminology as well.

CONTROLLED VOCABULARIES EXPRESSED AS LINKED OPEN DATA

Linked Open Data (LOD) are data created according to the best practices for publishing and interlinking structured data using the Resource Description Framework (RDF) syntaxes and made publically available on the Web; see <http://linkeddata.org/>. The Virtual International Authority File (VIAF), the Getty vocabularies, and the Library of Congress Thesaurus for Graphic Materials (TGM) are examples of controlled vocabularies that are made available as Linked Open Data in addition to their familiar formats as web lookup tools. Controlled vocabularies expressed as LOD can enable meaningful machine-generated linking, thus greatly enhancing the research potential of the online environment and enabling users to easily access related resources that they otherwise might never have found. Formats for expressing vocabulary data as LOD include RDF and JavaScript Object Notation (JSON). As of this writing, Bibliographic Framework (BIBFRAME) is the emerging data model for expressing bibliographic records using Linked Open Data.

CONCLUSION

The three main ways by which users attempt to find information online are browsing, directed searching, and following links.

For online collections of art, architecture, and material culture, all three of these methods can be extremely powerful. Museums can use their collection-specific thesauri and descriptive cataloging records to enable users who are unfamiliar with their collections to browse by object type, creation place, chronological period, subject matter, and so on. As shown in the examples discussed, directed searching can be significantly enhanced via both the terms and the hierarchical relationships in controlled vocabularies. Likewise, controlled vocabularies can be used to lead users to other materials of interest via links from one specific term or name to another. Many of the debates that are currently taking place among information professionals about how the library profession can modernize itself, compete with commercial search engines like Google, and ultimately not only survive but re-create itself center on authority control rather than on item-level description. The 2008 final report of the Library of Congress Working Group on the Future of Bibliographic Control (<http://www.loc.gov/bibliographic-future/news/lcwg-ontherecord-jan08-final.pdf>) also stresses the need

for increased focus on authority files and controlled vocabularies in a collaborative model among different institutions and communities, and the potential value of mapping values from different controlled vocabularies.

Controlled vocabularies, combined with less structured data values such as those generated by social tagging, may very well be one of the key elements in the future of access to the constantly growing body of online resources. Since the mission of museums, archives, and other collecting and memory institutions is not merely to collect and preserve, but also to provide access to what they collect, the use of controlled vocabularies to describe and lead users to their collections should be as essential as the use of security systems and climate control to protect and preserve those collections.

SPECIFIC VOCABULARY TOOLS

Following is a list of published vocabulary tools that can be used to describe and provide access to materials relating to the visual arts, architecture, and material culture:

Art & Architecture Thesaurus® (AAT)

<http://www.getty.edu/research/tools/vocabularies/aat/>

A structured vocabulary that contains terminology and other information related to art, architecture, and related disciplines. Updated monthly.

Cultural Objects Name Authority® (CONA)

<http://www.getty.edu/research/tools/vocabularies/cona/>

A structured vocabulary comprising unique numeric identifiers and brief records for works of art, architecture, and material culture. As of this writing, CONA is in pilot release phase.

Getty Thesaurus of Geographic Names® (TGN)

<http://www.getty.edu/research/tools/vocabularies/tgn/>

A structured vocabulary containing names and other information about geographic places, focusing on but not limited to places important to art, architecture, and related disciplines. Web version updated twice monthly.

ICONCLASS

<http://www.iconclass.nl>

A classification system for iconographic research and documentation of images. *ICONCLASS* is a collection of definitions of objects, persons, events, situations, and abstract ideas that can be represented in the visual arts. The system is organized in 10 broad divisions within which subjects are ordered hierarchically. Although

ICONCLASS is primarily a classification system, the textual correlates of the alphanumeric classification codes can be used to describe and/or index visual materials, as can the associated key words be.

Also available in print:

van de Waal, H. *ICONCLASS: An Iconographic Classification System*, 9 Vols., completed and edited by L.D. Couprie with E. Tholen, G. Vellekoop. Amsterdam, the Netherlands/New York: North-Holland Pub. Co., 1973–1983.

Library of Congress Name Authority

<http://authorities.loc.gov/>

A controlled vocabulary consisting of records for names and titles of works established by the Library of Congress and cooperating libraries. Updated daily.

Library of Congress Subject Headings

<http://authorities.loc.gov/>

A structured vocabulary designed to represent the subject and form of the books, serials, and other materials in the Library of Congress collections, with the purpose of providing subject access points to the bibliographic records contained in the Library of Congress catalogs. More broadly, LCSH is used as a tool for subject indexing of library catalogs and other materials (including visual materials). Updated daily.

English Heritage Thesauri

<http://thesaurus.english-heritage.org.uk/>

A set of thesauri developed by the National Monuments Record Center, English Heritage Project (officially known as Historic Buildings and Monuments Commission for England). The thesauri include Monument Types, Archaeological Objects, Building Materials, Defence of Britain, Components, Maritime Place Names, Maritime Craft Type, Maritime Cargo, Evidence Thesaurus, Archaeological Sciences, and a Historic Aircraft Types thesaurus.

Subject Index for the Visual Arts

Glass, E., comp. *A Subject Index for the Visual Arts*. London: H. M. Stationery Office, 1969.

A structured vocabulary used for subject access to materials in the Print Room of the Victoria & Albert Museum, London.

Thesaurus for Graphic Materials (TGM)

<http://id.loc.gov/vocabulary/graphicMaterials.html>

A thesaurus of terms that describe the subjects and the work types of graphic materials.

Union List of Artist Names® (ULAN)

www.getty.edu/research/conducting_research/vocabularies/ulan/

A structured vocabulary containing names and other information on artists, architects, and other creators of art and architecture. Web version updated twice monthly.

Corporate Archives

Philip Mooney

Heritage Communications, Coca-Cola Company, Atlanta, Georgia, U.S.A.

Abstract

Over 300 North American businesses support archival programs as part of their corporate structure. This entry provides an overview regarding the rationale for these archival programs, their organizational structure, the services they provide to the business, a sampling of internal marketing initiatives, and a description of the records contained in these collections. The entry also explores the differences between the work of corporate archivists and others in the profession.

While academic libraries, historical, and cultural agencies have collected voluminous records relating to the political, literary, and social history of North America, few repositories have included business collections as focal points of their acquisitions strategy. Certainly, institutions like the Baker Library and Eleutherian Mills at Harvard University, the Eleuthesian Mill Historical Society, the Minnesota Historical Society, and the Hartman Advertising Collection at Duke University have acquired very significant collections that partly fill the void, but the vast majority of American business records have been ignored by the major academic research centers. Consequently, the prime responsibility for preserving business records has fallen to the businesses themselves.

Corporations supporting internal archival programs tend to fall into three major groups: financial services companies including banks and insurance firms; consumer goods and services units; and technology-driven enterprises like. Representing the first group are companies like Aetna, Nationwide, State Farm, AIG, and Allstate from the insurance sector while Wells Fargo, American Express, Scotiabank, J.P. Morgan Chase, Royal Bank of Canada, and the New York Stock Exchange provide a wide range of financial services. Well-known consumer product companies include Ford Motor Company, Procter and Gamble, McDonald's, Walt Disney, Kraft, Coca-Cola, Eli Lilly, NBC, Williams Sonoma, Levi Strauss, UPS, and Gap. Technology-driven firms like IBM, Microsoft, and Hewlett-Packard also maintain their own collections.

Less than 10% of the Society of American Archivists 5000+ institutional and individual members manage business records, but business archivists have been an important component of the profession from the beginning. The Firestone Tire and Rubber Company formed one of the earliest corporate archives in 1943,^[1] just 7 years after the formation of SAA itself, and Firestone's archivist, William Overman, later became president of the society in 1957–1958. Since that time, there has been a steady increase in the number of companies supporting an archival

program growing from 133 business archives in 1969^[2] to nearly 350 in early 2008.^[3]

The single-most compelling reason for companies to create an archives is an anniversary of some note. As businesses reach significant milestones, documentation is required to provide historical context and to define those qualities and characteristics that separate one firm from another. Regardless of size or scope, anniversaries generate interest in creating a book, pamphlet, audiovisual production, exhibit, or some combination of those programs. The anniversary creates a unique opportunity for the organization to focus on its history and to allocate resources for the collection, organization, and utilization of its historical resources.

As these historic dates approach, many corporations realize that the records required to support commemorative programming are not easily found. Most likely, they are scattered throughout the business, disorganized, and stored in less than optimal conditions. The anniversary provides the catalyst to begin segregating these records and determining whether they offer a longer value proposition than the celebration of the anniversary itself.

A second driver for corporate archives, frequently connected to the first, is the CEO initiative. While corporations are normally forward-looking and disinclined to consider history as a relevant element in strategic thinking, senior managers want their legacy to be preserved and to become imbedded in the corporate culture. As leaders approach the end of their term in office, they become much more reflective on their accomplishments and much more inclined to take positive steps to see that those achievements are institutionalized. The CEO archival mandate is more common in family run enterprises but such initiatives can occur in businesses of any size. An archives stands as a visible reminder to both internal and external audiences of the legacy that has been established.

Litigation support and the recognition of an information gap are the other factors that can influence the foundation of an archives. In order to protect trademarks and

other forms of intellectual property, corporations must have detailed files that document the creation and utilization of their advertising concepts and campaigns, packaging, technology, and marketing initiatives. In many instances, an archives charged with the collection and management of these materials offers the best low-cost option for protecting these assets.

Similarly, an archives provides a unique resource for the business that other information management specialists do not provide. The archivist looks across the entire spectrum of records being generated by the parent body and determines which materials have long-term value to the ongoing work of the business. In most cases the total volume of retained records is no more than 2–3% of all records generated, but the retention of those materials will define what future generations know about the organization and can help to educate new managers, agencies, and suppliers about the core principles that define the brands and programs they direct.

Once a decision has been made to create an archives, the placement of that function within the business becomes the next critical decision. Most corporate archives reside within one of four areas: the public relations or communications function; the office of the general counsel, the corporate secretary's office or some administrative placement such as the president's office. All of those scenarios can work well as long as the decision-making ladder is relatively short. If the archives has easy access to senior management for resources, allocation, a specific organizational structure is less relevant.

Still, there are some positives and negatives to be considered in any of these arrangements. The communications placement may be the most symbiotic as both archivists and public relations professionals respect and appreciate the power of information. The communications function has a broad view of the organization and provides enhanced visibility for an archival program. The principal drawback to this linkage is that the public relations activities are often ranked lower than other functional areas and frequently receive lesser funding. Ties to the General Counsel or to the Corporate Secretary's office place the archives in areas that are well regarded and operate from positions of strength. Funding for programs is easier to obtain and access to senior management is streamlined. The potential negative in this placement is that the archives can be easily neglected because of critical business priorities facing the functional leadership. The most dangerous positioning is the administrative one. This situation usually occurs if a President or Chairman has made a unilateral decision to create an archives to preserve the history of a specific administration or when the archives is dumped into a general administrative area that handles nonessential business activities. In this scenario, the archives is the likely victim in a change of executive leadership or a financial slowdown that necessitates a prioritization of resource allocation.

Corporate archivists will often create a wide array of tools to help them attain greater visibility in the corporation and to better define their role. One of the most important documents for a corporate archives is a mission or policy statement, distributed company-wide, that defines the responsibilities of the department and provides the authorization for the archives to collect records from individual business units. Such documents may detail the specific functions of the archives, may identify records considered to be archival, and may even outline the specific processes for transferring records to the archives.

The creation of a broad-based, cross-functional advisory board to help the archivist define the institution's collecting canons can broaden the client base of the archives and develop an in-house support system for its mission. By holding regular meetings of this group, the archivist ensures that the collection represents the company's key functions while creating a group of auxiliary archivists with a vested interest in securing important records from their respective functions.

Many archivists place a high priority on outreach programming to extend the influence of their institutions to external audiences, attracting new researchers to their collections and generating a broader support base for their activities. In the corporate world, outreach is also critically important, and the overall objectives are similar, but the tactics and execution are internally directed. Unlike academic programs where the value of preserving historical documentation is clearly understood or government repositories where retention is mandated, corporate archives exist in an environment that focuses on the future and pays little more than lip service to the past. To succeed over the long term, the corporate archives must be relevant to the business and be able to justify the costs of the program.

One of the most natural alliances is with the public relations team as the archives is a tremendous resource for the generation of media coverage of the business. The archives can provide the historic background data, photographs, film, and video that add depth and color to the new releases and media stories that shape the image of the business to the outside world. The archives provides content to in-house magazines, newsletters, annual reports, social responsibility, and citizenship publications that communications groups produce and distribute. Additionally, the archivist can become an adjunct member of the public relations department by authoring features on heritage and serving as a company spokesperson on historical issues.

During an anniversary celebration, the archives becomes even more critical as it serves as the primary resource for the publications that will inevitably mark the event. Books, magazines, case studies, timelines, brochures, and pamphlets signal important milestones in organizational growth and development and create special opportunities for the archives to shine in the corporate spotlight. During these

moments of historical focus, the relevance of the archival program is obvious. It is in the nonanniversary years that a program must have a broader organizational impact to sustain itself.

Technology offers new possibilities to make archival materials more accessible to broader audiences. The emergence of digital technology allows users access to thousands of images, documents, and audiovisual materials via intranet sites. With a few clicks of a keyboard, materials that had been held in a single geography can be shared with associates in hundreds of locations in high-resolution formats, resulting in cost-savings that can be calculated and communicated to the management. Similar techniques are used throughout the archival profession, but the business archives application has a robust revenue stream that establishes a clear return on investment (ROI), a calculation that every business recognizes and appreciates. Many business operations rely on a network of agencies and suppliers to provide them with high-resolution photography files for commercial applications at costs that frequently exceed \$100 per unit. The existence of the archives removes these middlemen and concentrates the collection and preservation of images at a single contact point, supplying materials through the organization in a cost-efficient manner. In addition to the information sharing, many corporate archives license their images to third parties for commercial application. These licensing programs generate thousands of dollars that can reduce, if not totally offset, the costs of maintaining an archives.

The Internet also provides business with an interactive communications tools to reach out to important constituencies: consumers, stakeholders, students, the media, regulators, and nongovernmental organizations. A section of the site devoted to Heritage can provide a large volume of useful information to individuals and groups interested in the historical and cultural impact of the firm. By placing this data in one convenient location, the business connects with key audiences while gaining some cost-savings through the reduction of personnel handling consumer inquiries.

The use of blogs as a social media tool offers new opportunities for corporate archivists to engage proactively, using rich content from their collections on the Web. Rather than relying on traditional media outlets to publish positive stories on the history of the business, archival bloggers can post stories and commentary on a schedule of their choice and can interact with groups and organizations that would not normally receive information directly from the business. With over 100 million blogs in existence, an archival blog may be one of the easiest methods of delivering historical information through nontraditional outlets.

Exhibitions are excellent tools to enhance the archival presence, signal the importance of history to the organization, and create an experience that helps shape the corporate culture. Most corporate archives use them, in one

form or another, to create an atmosphere that encourages the study of the past to inform the future. The size and scope of these exhibits can vary from small window and case displays near the archives entrance, to more robust lobby displays greeting visitors to the business, to free-standing museums open to the general public, but the archivist administering these share one strategic objective. The exhibit makes history and the archives come alive for the people reviewing it, providing an overt rationale for the larger program.

Within the marketing arena, the archives can play a pivotal role in helping managers understand business and brand basics. By securing a representative collection of advertising, promotional, packaging, and product files, the archives can document the strategies, positioning, and philosophies that have marked both successful and unsuccessful programs. Management can then repurpose the best practices into contemporary executions that will resonate with consumers. Conversely, by understanding why projects failed, there is a stronger likelihood that a new generation of management will not make the same mistakes.

As noted earlier, one of the reasons businesses choose to establish archives is their critical role in litigation. Trademarks, patents, designs, copyrights, and other forms of intellectual property uniquely define the corporation and represent its most valuable assets. By maintaining records of the development, implementation, and continued use of those elements, the corporation secures its unique standing in the marketplace and ensures its long-term viability.

The archives serves as a powerful resource in this arena. The scope of the collection itself can frequently discourage frivolous lawsuits from ever being filed, but the more quantitative value is established when records maintained by the firm form the basis for a successful legal action. All of the costs associated with the creation and maintenance of the archival program could be recovered with a single piece of litigation.

The human resources function represents yet another client for archival services. Employee orientation presentations, training programs, department briefings, and retiree organization all benefit from an in-house historical department that can supply materials that underscore the company's mission statement and reinforce those values that shape the corporate culture. Frequently, the archivists play a pivotal role in such activities, while the films, photos, music, videos, and artifacts from the archives add depth and color to the presentations.

The types of records collected by corporate archivists are similar to those collected by any other repository that collects institutional documentation, but the volume of records generated by business and the sensitivity of certain categories of records (personnel, financial, research, and development) requires rigorous appraisal criteria. The nature of the business itself and the frequency of use are

the two primary criteria that determine the volume of materials collected and the hierarchy assigned to them. A financial services company will tend to collect records with fiscal content more heavily than a consumer goods company that will focus more energy against identifying and securing marketing and advertising files. Not only are those records more indicative of the functions of the respective businesses, they also are the records used most frequently by business units.

Conversely, corporations generally will not retain certain record types as part of the archives if they have high litigation potential. Federal and state regulations mandate the retention of specific personnel, technical, and financial data, but at the expiration of the required life cycle, these materials will be destroyed unless there is a more compelling historical reason to retain them. In an era when class action lawsuits can yield millions of dollars in settlements, corporations will not run the risk of preserving records of tangential research value.

Most corporate collections will include records from the senior executives of the organization. The papers and working files of the Chairman of the Board of Directors, the President, the Chief Financial Officer, and the Corporate Secretary's office will provide a strong overview of the events and issues that characterized each administration. Functional records from Finance, Legal, Human Resources, Technical, Public Relations, Community Affairs, and Administration provide the detailed documentation of the operations of the enterprise that will comprise the historical record and allow for interpretation and repurposing in the future.

In developing an organizational scheme for the records, corporate archivists look at the work product from each group and establish record groups that document their activities. For instance, a record group titled Marketing would contain data relating to the advertising, promotion, and packaging of goods and services. A Human Resources record group would contain data on the workforce, policies and procedures, training information, and employee benefits. The record groups will vary in size and importance depending on the focus of the business, but they should reveal the essential activities of the parent body.

The collections will also hold extensive audiovisual collections, clippings files, small library collections, and reference files, as well as the records of predecessor or merged companies that may have their own unique records structure. Many archives will also function as the corporate museum and will preserve extensive collections of artifacts encompassing packaging, awards, promotional items, premiums, and a host of advertising and marketing samples, ranging from small signs and posters to large pieces of equipment.

The biggest differences between the work of corporate archivists and others in the professional falls into three areas: descriptive practices, access policies, and the institutional approach to reference and research. While most

archives are interested in fully describing their collections and making them available as broadly as possible, corporate programs have a very different vision. Their clients and users are the employees, suppliers, and business partners of their host institution. Their mandate does not extend to any third parties beyond that limited definition.

Many corporate archives have sophisticated information management and digital asset management systems that allow them to share detailed information about their holdings internally and externally, but they seldom report or contribute to national databases that make similar information available to researchers around the world. The corporate archivist does not seek or encourage the external researcher who would certainly materialize if holdings were more widely reported. Similarly, the descriptive tools used by the archivists are designed for internal use and frequently are based on proprietary software developed by the business itself.

Most business archives limit access to the collections to employees and designated partners. They do not solicit or cultivate scholarly research nor do they feel obligated to share their resources with the general public. The corporation provides all of the funding for the program and determines how the collection will be used. Equal access is not a concept utilized in the corporate environment.

The archives receives funding because it provides a unique set of services that the business could not secure from any other source. It is intellectual capital that is as important as trade secrets or patents. Consequently, there is a reluctance to share this collateral with others by opening the doors of their historical vaults to the outside world. From the corporate perspective, there is little to be gained and a very serious downside to releasing materials to third parties who do not have a vested interest in the business.

Reference and research also look considerably different from academic models. In academic settings, researchers travel to the host institution, request the desired records, study the documents, and formulate their conclusions. Reference specialists respond to written and oral inquiries in a structured fashion that normally requires the researcher to wait several days, if not weeks, before receiving a formal reply.

In business, the archivist processes the records, prepares finding aids for them, and then assumes all of the research and reference responsibilities. As to the subject matter expert, there is an expectation that the archivist will search through the records to expeditiously retrieve the requested information and deliver it to the client. Researchers seldom visit the archives and even less often volunteer to go through the materials themselves. There is the further expectation that the requested information will be provided in a time-sensitive fashion measured in minutes and hours rather than days and weeks. Businesses operate on cycles that require speed and efficiency to produce financial results that benefit their shareowners.

Archivists operating in that environment must mimic those qualities if they are to be successful.

Salaries for business archivists tend to be higher than those of other archival practitioners. The mean salary for academic archivists hovers around \$50,000, while government archivists earn about \$3000 more. The mean salary in the business arena exceeds \$61,000, with manager salaries approaching \$70,000.^[4] Additionally, compensation packages in corporations frequently include annual bonuses and stock options not reflected in the salary figures. Total compensation in the corporate sector can easily exceed \$100,000 per year.

While the compensation levels for the corporate archivist are appealing, this segment of the profession is the most unstable. The continued existence of the program totally depends on the financial health of the parent organization. In years of strong earnings and profitability, the archives will prosper and enjoy management support, but in an economic downturn, the first targets of downsizing are those functions considered overhead. Unfortunately, archival programs can be consigned into this category, resulting in reduced, outsourced, or discontinued programs. Some of the major business archives programs in the United States including those at Firestone, United Technologies, Arco, Bank of America, and Polaroid disappeared in retrenchment initiatives.

The number of business archives in North America will probably continue to grow though not as rapidly as

programs in the nonprofit sector. For current information about business archives, the best resource is the Web site of the Business Archives Section of the Society of American Archivists (<http://www.archivists.org/saagroups/bas>). This site includes member's profiles, news and announcements, information on section initiatives, and technical guidance on issues of concern to the group. Dr. Gregory Hunter, a professor at Long Island University, maintains the "Directory of Corporate Archives in the United States and Canada" at his Web site (hunterinformation.com), and Dr. Hunter also posts the notes of the Corporate Archives Forum there. The CAF is an informal group of about a dozen business archivists from large companies who have met annually since 1998 to discuss issues of mutual interest and to share best practices. Additionally, the Society of American Archivists sponsors a workshop on Establishing and Managing a Business Archives on an annual basis.

Corporate Art Collections

Laura Matzer

Arizona Museum for Youth, Mesa, Arizona, U.S.A.

Abstract

What propels a for-profit corporation to collect and invest in the collection management of an art collection, to buy original works of art to display, care for, and store? What are the benefits of placing art in the workplace? What does the future hold for corporate art collecting? The term “corporate art collection” has become a generic, catchall phrase that often encompasses the art collecting activities of law and accounting firms, small companies, government, cities, port authority, transit, and other types of organizations. The purpose of this entry, however, is to discuss art collecting activity conducted within corporate business workplaces specifically. Does a corporate art collection reveal a corporation’s viewpoints, long-term goals and aspirations, and culture? And what are the philosophical concerns of mingling art and commerce in the presentation of art in a corporate setting? This entry seeks to address such questions and provide a cursory history of corporate art collecting in the United States and abroad.

INTRODUCTION

The notion that to place art in the workplace is simply *decorative* is to take a simplistic viewpoint. Corporations buy artworks to fill many needs: to fill blank walls, to improve a *workplace* environment, to enhance their *image* (internally, externally, or both), to support the local art community, to make a social statement, and to demonstrate their company values.^[1] While most companies do not purchase art for financial gain, some track the current market value of their collections for insurance and other purposes. For many corporations, *accessibility* and image are key elements in the contemporary world of corporate art collecting.

An emphasis on contemporary art seems to be a trend in corporate art collecting, the currently high-paced—and priced—art marketplace notwithstanding. Popular amongst companies with a *global* presence, is to collect art with an international focus, reflecting their workforce, or reflect a *regional* art focus in specific locations. Corporations today are particularly savvy in finding new ways of utilizing their art collection for *marketing*, advertising, and *commissioning* artwork to promote their company’s image and products.

Every corporate art collection, from its origins, to its objects, to its operations, is unique. There currently remain very few books and articles written on the subject of corporate art collecting. While the *Directory of Corporate Art Collections* profiles over 1000 collections, and some companies promote their art collections and attendant activities online and in print, much remains hidden and private in regard to how corporate art collections are formed, managed, and maintained. This entry aims to illuminate the world of corporate art collecting.

HISTORY

The collaboration between art and business dates back to Renaissance Italy and in more recent years has become a common partnership.^[2] In earliest examples, financial institutions were leaders in terms of corporations collecting art; presenting art in the workplace demonstrated to their clients the sophistication and wealth of their institution, as well as the path of portfolio investment. Deutsche Bank, one of the largest corporate art collections in the world at present, has over 50,000 objects in their collection, housed in over 1000 locations. Regardless of institution type, the history of each corporate art collection can provide a fascinating glimpse into the history and culture of a company. Many corporate art collections were willed into being by notable CEOs with personal interest in art and art collections of their own, and a vision for wanting to bring art—and the appreciation of culture that comes with art—into their corporate culture. Others begin their art collecting activity by forming grassroots committees of interested executives and employees.

In the United States, in late nineteenth and early part of the twentieth century, art was explicitly used for marketing: railroads such as Union Pacific and Santa Fe would use art as a publicity medium to encourage travel and to publicize themselves.^[3] Abbott Laboratories began their collection in 1930, the Anheuser-Busch collection dates back to the late 1890s, and what is generally regarded as the first modern-day corporate art collection is the International Business Machines (IBM) collection of contemporary American art, begun in 1939.^[4] Image making continued to drive art collections that began in the 1960s and the 1970s, with a large number of collection facilities being created in Japan. The 1980s witnessed a significant

rise in corporate art collection activity, particularly in the United States and Britain. By the 1990s, as a result of an economic recession, some corporate art collections disbanded or were sold, leading many to consider corporate art collecting as a mere phenomenon of the times. In fact, the sheer number of corporations collecting art on an ongoing basis far outweighed the few collections that were dismantled. Today, corporate art collecting is now an “established segment of the art world, with its own corps of professionals and specialists, its own philosophies and standards of ethics, and its own professional organizations” (Fig. 1).^[3]

In Europe, with more general, broad-based government support to museums and artists, culture is more widely considered a part of life. With this intrinsic way of thinking, European corporate art collections have been innovators in terms of collecting activity, commissions, and corporate-supported artist projects. The Deutsche Bank art collection was essentially founded on a friendship. Herbert Zapp, a former bank board member, lent his chauffeured limousine to the artist Joseph Beuys while Zapp drove an accompanying security car, en route to a Beuys exhibition, and they became friends. Another board

member, Hermann J. Abs, years previously, had introduced Beuys to the bank. Together Abs and Zapp shaped the bank’s art policy in the 1970s, and jointly initiated a significant acquisition of a comprehensive series of Beuys drawings for the Deutsche Bank art collection.^[5]

In addition to placing art in the workplace, some corporations have designated spaces solely dedicated to displaying their collections in corporate art museums, galleries, and sculpture gardens. The first corporate art museum was founded by Josiah Wedgwood & Sons Ltd. in 1906 in Barlaston, Stoke-on-Trent, and other corporate art museums and galleries began to proliferate in the 1920s.^[6] By the 1990s the corporate art museum model was challenged. Occidental Petroleum Corporation’s Armand Hammer Museum of Art and Cultural Center in Los Angeles was created in the late 1990s, which brought about lawsuit from dissident stockholders challenging the right of Chairman Armand Hammer and the Occidental Petroleum Corporation to finance a museum housing the chairman’s private collection of artworks. The lawsuit further charged that the museum had no tangential connection to the company and offered no stockholder benefit. While a settlement was reached, the ruling was in line “with long-time corporate beliefs and practices in the United States and other countries” that spaces can be created if the facilities are in the best interest of the company, “on the grounds that it is in the company’s best interests—meaning good for business and public relations.”^[6]

PROMOTING CULTURE

Although internal and external publicity varies amongst them, corporate art collections typically exhort the role they play in promoting arts and culture in their respective workplaces. They have many reasons to do so: In addition to directly supporting artists through tangible object acquisitions, their collections also can be considered a valued intangible asset for the public relations of a corporation that supports a professional and inspiring environment for employees and the public. Regardless of intent, a corporate art collection serves as an ongoing visual reminder of the value of inspiration, creativity, and innovation, and the corporation’s support of such values. That said, there are numerous philosophical issues surrounding the intermingling of art and commerce, as companies that delve into art collecting, art sponsorship, and other modes of engagement, can “convert cultural capital into economic capital, in sometimes politically pernicious forms.”^[7]

Responses in a 2001 survey of 32 companies by the Business Committee for the Arts (BCA) and the International Association for Professional Art Advisors (IAPAA) assert that art in the work environment fosters elements essential to a company’s success. The survey found that 78% of respondents believe that art in the workplace

reduces stress, while 64% believe it increases creativity and productivity. Another 67% believe it enhances morale, while 77% agree that it “broadens employee appreciation of diversity and encourages discussions, and expression of opinions.”^[8]

ACQUIRING ART

Corporations acquire artwork for their collections in a number of ways. In fact, there is a constellation of entities that can be involved in any one corporate art program. Some companies employ in-house curators, who work with decision-makers in their company and outside resources—such as art galleries, artists, auction houses, and print publishers—to select works of art. Other companies outsource art advisors to recommend artworks to a decision-making committee or individual within the company. Depending on the project, an in-house art curator or an outsourced art advisor can work with architects, landscape architects, contractors, lighting designers, and building occupants to determine an art installation plan, proper lighting, and architectural opportunities for special art placement.

The type of art purchased on behalf of a corporation is as varied as the companies amassing them. Some corporate art collections purchase and commission art tied to their products or marketing campaigns, while others collect and commission artworks intended as visual counterpoints to the workplace environment. Most corporate art collections have a mission or vision statement to guide their collecting activity and programming. Ultimately, corporations that collect and display art in their facilities are stating, either overtly or subtly, that they support culture within and without the workplace walls.

For artwork acquisitions, regardless of purchase decisions made by committee or by those considered subject-matter expert(s), such decisions require research, timing, and negotiation. In most cases a rigorous initial selection process is undertaken. Corporate art curators and art advisors can consult numerous sources: art fairs, museum exhibitions, art journals, newspapers, magazines, artist monographs, art galleries, exhibition catalogs, juried exhibitions, and artist studio visits. When a work of art is purchased, items such as shipping, framing, digital image, accession number, provenance, artist and exhibition articles, artist curriculum vitae, gallery announcements, and condition reporting are just a few of the items that go into the typical processing of an artwork as an asset into a corporate art collection.

Those that purchase the artwork, in addition to keeping in mind the project’s budget, building installation plan, hanging or placement requirements, have many other variables to consider when deciding upon what to buy. The famous dictum to “buy what you love” is a good rule of thumb. However, the purchaser’s (or decision-maker(s)) taste and aesthetic is a factor, as well as, content of the

piece, media, style, artist, size, installation requirements, price, and expected maintenance. Further, it is the job of the procurer to examine the strengths and weaknesses of an existing art collection and how a new acquisition would fit within that collection. Other items that a purchaser will likely weigh are authenticity, historical significance, provenance, practicality, region, and ethnicity of artist.

When a project’s scope is assessed, the individual(s) determining artwork purchases can look to the primary art marketplace: art galleries, artist studios, rental/sales galleries, and to the trade commercial art procurers, or, to the secondary art marketplace: auction houses and consignment art galleries. In addition to filling their buildings with artworks, many companies also commission artists to create site-specific works in designated locations within their facilities. Commissioned work gives the company an opportunity to have an iconic, unique piece of art to both support artists and to enhance their image. In a recent example, BMW commissioned Icelandic artist Olafur Eliasson, an artist concerned with tangible topics such as civilization, technology, and nature, as well as renewable energies, and ephemeral works, to design the 16th BMW Art Car, to be added to the BMW Art Car Collection.^[9] Eliasson’s work, an H2R BMW metal car frame covered in 2 tons of frozen water and lit from within, is a sharp visual commentary intended to raise awareness to automotive industry practices and their effects on global warming. His work, which initially may seem an indictment of the automotive industry, ultimately aligns with BMW’s values for their product, which is to provide sustained mobility based a regenerative fuel source.

While modern day media may obsess upon corporate art collections that have been disbanded or sold, corporate art collecting comprises a large segment of the art marketplace—some attribute up to 30% of sales worldwide toward this specific market—however it is difficult to fully assess as many dealings are kept secret.^[7] For artists interested in their work being added to a corporate art collection, F. David Fowler, managing partner for KPMG Peat Marwick, who works with the art advisors for their corporate art collection, states:

The key to being included in a corporate collection is no different from being in an outstanding private collection: you have to be known, have a good gallery. A typical corporate art curator or art advisor gets invitations to every gallery opening in town, every exhibition and show, but it is tough. . . I wish we could do more with local artists but budgetary constraints limit us.^[4]

ART AS INVESTMENT

While there have been certain art collections that have applied an art as investment philosophy to their collecting

activity, by and large, most corporations do not buy art for investment. While artwork typically appreciates in value rather than depreciates, and corporate executives may find satisfaction in that fact, corporations that are in the position to begin or support a corporate art program typically have a product or products that bring in significant profit, so looking to an art collection as a potential money-making investment is not typical. One challenge to a corporate art program is to demonstrate, particularly in a tenuous situation, such as a company merger, executive shuffle, bankruptcy, or buyout, that the collection's value is equally high, if not higher in intangible value to employees, customers, and visitors that interact with the art collection on a daily basis.

For a publicly held company, another concern is how a corporation's art collection is viewed amongst its stockholders. While it has been demonstrated in studies such as BCAs aforementioned survey in 2001, and in other sources, that art in a workplace environment improves productivity and employee satisfaction, stockholders may question putting company profits toward such a program. Conversely, stockholders may appreciate that artworks are a part of a company they have invested their hard-earned money in: The company invests in benefiting employee quality of life and the art community.

COLLECTION MANAGEMENT

As we have by now well established, every corporate art collection is different. So is how they are managed: One particularly large corporate art collection can have 10 different curators with various content specialties, and a smaller art collection could be overseen by a director in lieu of a curator. Corporate art collection management has been humorously described as a cross between being air traffic controller and the director of an art museum. When corporate art collections begin, collection management can sometimes be an afterthought. However, when a corporate art collection grows to a certain size, it becomes abundantly clear that professional collection management is required. Benchmarking survey data from similar-size art museums and corporate art collections can demonstrate strengths and weaknesses in a corporate art collection program assessment.

Important items in collection management that a corporate art collection typically requires are collection management database to store and track data; climate-controlled art storage facility; de-accessioning (*to sell or otherwise dispose of an item in a collection*) of objects; conservation; image library; art research and reference library; appraisal and inventory survey of collection; and maintenance schedule for cleaning select works, such as outdoor sculpture. Unlike a museum collection, which may house up to 90–95% of its holdings in storage at any given time, a corporate art collection is usually the

Fig. 2 View of Microsoft Art Collection storage vault.
Source: Photo courtesy of Microsoft Art Collection.

opposite ratio, and the works are typically rotated within buildings owned by the company (Fig. 2).

A corporate art collection might be housed within any number of teams or departments. These can range from Human Resources, to Real Estate, to Legal, to the Executive Office, depending on how a particular company's divisional structure is arranged. Furthermore, every corporate art collection budget is unique. For a growing company, an artwork budget might be set by a metric, or measurement, involving square footage. For others, it may depend on the desire of the CEO.

ALTERNATIVE MODES OF COLLECTING

Corporations also instigate other types of involvement with artists beyond the corporate art collecting model. For art collections that become a valued and invaluable part of a stable company, many companies utilize their collections in targeted marketing campaigns, advertisements for products, and commissioning artists to literally make a mark on their products. Examples of this are seen in commissioned works for Illy Espresso company and wine labels for Baron Rothschild wineries. New forms of corporate sponsorship will continue to emerge and set trends, as the worlds of marketing and advertising, art and commerce converge.

Corporate Mentality, a book by Swedish artist Aleksandra Mir, documents the myriad ways in which artists interact with corporations and how they consider them rich subject matter in producing object-based and performative artworks. In one example of art meeting

commerce, Mir interviews Martina Westin, Manager of Communications of The Absolut Company in Stockholm. Remarks Westin:

The artists that collaborate with us are given complete artistic freedom. . . we don't buy art, but look for a relationship in which we ask artists to interpret our (vodka) bottle. In that, they are free to do whatever they like but . . . since many of the art works are advertised, some policies and laws apply, such as no cars, no children and no pornography. That way freedom of expression may be limited, but our parameters are clearly stipulated from the very beginning when we brief the artist and he/she accepts or enters the collaboration. . . Maurizio Cattelan's rat in the bottle. . . I tell you, I have worked in the food industry for many years, and rats in conjunction with food is the ultimate no-no. But here we felt that the artistic freedom and the integrity of the artist is important, so we approved it.^[10]

Created in 1984, Fondation Cartier Pour l'art Contemporain, in Jouy-en-Josas, France, has a unique program that is a separate division of Cartier International Paris. Their foundation, historically the first corporate foundation in France, provides studio, living, and exhibition space for artists-in-residence, as well as a conference and meeting center, library, restaurants, sculpture garden, and an exhibition hall. Other corporate art collections innovate through programs training employees to lead art tours, inviting artists to speak, presenting films, offering art-related book discussions, and developing partnerships with community organizations and more.

Umeå Energi, located in northern Sweden, produces, distributes, and sells electricity, heating, and cooling. Collaborating with Umeå's College of Art, they work with students to create various art projects that are featured in differing formats for company use. Mir's interview with Anette Mångsén discusses their "Power Flower" project. States Mångsén:

Power Flower is a sponsorship arrangement that . . . is an example of how art can be used for more than just adornment. The agreement. . . also gave us the right to use the Power Flower theme in our advertising, in our information activities for schools, on our Web site. . . on T-shirts, and as a screensaver, etc. This is how sponsoring works. It should involve mutual giving and taking, in which both parties are winners. . . a sponsorship agreement is just like any other business arrangement. By means of artistic expressions. . . we can demonstrate that Umeå Energi is more than electrons and incinerators, and that we are people with warmth, feelings, and a sense of humour. Employees also benefit from seeing art in their everyday lives. We spend a large proportion of our working hours at work, and it is important to have various forms of stimulation. Art is enriching, and it liberates the senses.^[10]

Another interesting model is the collaboration of BMW KulturKommunikation unit and the BMW Art Car

Collection. Christiane Zentgraf, head of, Corporate Affairs, in Munich, Germany, states:

The BMW Group has been actively engaged in the field of culture for over a quarter of a century, both regionally and internationally. Over the course of time, BMW's experience with art led to the realization that a discursive engagement with art and culture, if it is used in the right way, can be employed as an outstanding medium of communication. Art and culture are highly sensitive fields. Our primary focus is not on financial transactions or the cash value of goods, but rather the long-term interaction of partners who are interested in getting to know and understand each other and each other's worlds, exchanging ideas, and realizing joint projections that will, of course, need to be financed. The widely quoted motto, "Do good and talk about it," is not BMW's policy. BMW believes in "doing good and letting others talk about it."

The BMW Art Car Collection began in 1975 as a result of the spontaneous request of French auctioneer and racing driver Hervé Poulain to his friend Alexander Calder to design a BMW racing car. The idea "sparked enthusiasm in both Calder and BMW," and started the impetus for additional art cars by artists such as Roy Lichtenstein, Frank Stella, Andy Warhol, Jenny Holzer, and Robert Rauschenberg. Zentgraf further states: "The artists find themselves in the world of automobiles; BMW is critically received in the world of art."^[10]

CHALLENGES AND CONCERNS

Some corporate art collections strategically aim through their artwork acquisitions to challenge the viewer. Others are tied to the initial vision of a CEO, such as Lloyd Cotsen's textile and folk art collection at Neutrogena (today housed in a wing of the International Museum of Folk Art in Santa Fe). Regardless of acquisition focus, by and large, those purchasing works for corporate art collections do consider sensitivity to subject matter, in light of the fact that employees are paid to be at a workplace vs. an individual willingly experiencing a boundary-breaking art exhibition. Many corporate art collections, such as Microsoft's, while pushing certain envelopes, often, do avoid artworks with overt nudity, political and religious content. Works of art with challenging media, such as materials that are highly light-sensitive, hazardous, or sculptural works with dangerous shapes must also be considered prior to being placed in a workplace setting.

As a corporate art collection grows, the overall value of the art collection can appreciate to the point that a specialized fine art insurance policy is required. In larger businesses with offices worldwide, it can be a challenge, however, to demonstrate the level of risk a company is exposing itself to if the company is large enough to deem such a specialized policy irrelevant. Many corporate art

collections are difficult to formally survey and appraise, as artworks can be installed far and wide depending on the corporation's size and their art collection's overall program and scope. Finally, there are a number of legal concerns that a properly managed corporate art collection must consider, such as loaning objects to art museums and institutions; rights to reproduce images of works in the collection in various formats (print, online) and for various uses (education, commercial/advertising, product packaging); and bill of sale for purchasing artworks from primary and secondary art marketplace sources.

CORPORATE SPONSORSHIP AND PATRONAGE

With the seemingly gradual reduction of governmental funding, particularly in the United States, arts institutions increasingly turn to corporations and other sources for short- and long-term support. Through arts sponsorships, corporations gain new audiences and new platforms to market themselves, which has “become a well-known and beneficial marketing tool.”^[11] Deutsche Bank is a major sponsor of the Frieze Art Fair in London, and also operates a space—the Deutsche Guggenheim—an outpost in the Guggenheim Museum's global network on the ground floor of the Deutsche Bank building in Berlin. Corporations can also make an impact in rural areas or small- to medium-sized cities, such as Microsoft's campus in Fargo, North Dakota, if they are acquiring and placing art and can directly impact a regional art market, from individual artists to art galleries and collaborations with local art museums.

Corporations that support the arts, not just in corporate art collecting, but through sponsorship and other innovative programs, have often been compared to the Medicis:

Why don't more people buy art? The benefits are considerable: offices have to be decorated anyway; it pleases and motivates the workforce; it enables a company to project a positive image and to act like a Medici, sponsoring artists; and not least, careful buying can prove a profitable investment.^[11]

See Fig. 3 for an illustration. With some companies their art collection is an integral part of the culture of the company, yet for others, there is also the drive to affiliate themselves with artists to market their products in new ways. Takashi Murakami's collaboration with Louis Vuitton on their monogram handbags demonstrates that boundaries between art and the commercial sphere can easily blur. Aforementioned Olafur Eliasson also created a light piece for Louis Vuitton stores, and, almost defensively, states:

It is about a principle that art should not be exclusive. Art doesn't have to polarize itself into a critical, quite

Fig. 3 Select corporate art collection sizes in object totals, August 2007.

predictable role of being oppositional. To think that a museum is a free space and a Louis Vuitton window is not is problematic.^[12]

When LACMA opened its 60,000 ft annex, the Broad Contemporary Art Museum, in February 2008, real estate financier Eli Broad gave the museum \$50 million for construction, and limited access to his foundation's art collection as well as his personal one. This hybrid arrangement, of which there are a few other examples, presents the viewer with a potentially confusing presentation of a museum within a museum. Finally, corporate executives with a passion for art have long held posts on museum boards and advisory committees, not only for their ability to donate to the institution, but also for their access to others with similar interests and pocketbooks.

EVOLUTION OF THE WORKPLACE

The corporate workplace is rapidly evolving, as evidenced at Microsoft, with more employees working remotely and the proliferation of open plan workstations, which decrease the overall amount of available wall space to hang artworks. For those that maintain an office, many employees no longer adhere to a 9 A.M. to 5 P.M. work schedule; some utilize their office spaces 24/7. In addition to these developments, many companies choose to “brand” their interiors with company logos, products, awards, and advertising campaigns. As a result, placing art in the dynamic setting that is today's workplace requires nimbleness and open attitude to change.

In a workplace environment, artworks are subject to a variety of variables not found in a more controlled art museum setting. Fluctuations in light, temperature, and humidity, which vary depending on the heating and cooling system activity in an office building (on weekends such systems are typically powered down) must be considered regarding art installations. Other elements, such as mail carts, construction projects to retrofit interiors, painting

crews, furniture moves, all must be considered and planned for prior to art placement. Furthermore, most corporations do not have the level of security one might find in a museum setting. Corporations with art collections can counterbalance security concerns by security-mounting artworks and educating employees through programs and signage about appropriate behavior with regard to looking at art.

Due to the proliferation of technology in the workplace, placing art within such a context can strike a powerful visual counterpoint against a field of varying devices. In such a setting, art can humanize the environment, make a statement, and enhance a company's overall image. In the United States, one way corporations evaluate themselves and each other and how employees evaluate them, is through the Fortune Magazine's "Best Places to Work" survey. A company-sanctioned art program can attract future employees and retain existing work force, as a corporate art program can overtly or subtly demonstrate the environment of the corporation and how the company treats its employees.

CONCLUSION AND LOOKING FORWARD

There have been gradual and significant changes to the world of corporate art collecting. Many companies that are expanding are expanding their art programs as well, and new companies continue to start their own art collections. The often more conservative art collecting programs in the 1960s and 1970s, leading up to the extravagant purchasing in the 1980s—and wholesale selling of certain art collections during economic downturns—led to today's cautious, yet carefully optimistic and predominant viewpoint of corporate art collecting reflecting the values of a company. Corporate art collecting is now an established entity in the art world, with a variety of professional organizations to support specialists in the field.

As corporate art collections grow, some companies will consider establishing a nonprofit foundation to protect their collections from oftentimes tumultuous business cycles and executive turnover in a company.

One interesting model has emerged from Hallmark Cards, Inc.: After having built a museum-worthy photography collection, the company donated it in 2006 to the Nelson-Atkins Museum of Art for posterity and to enhance the museum's photography collection holdings. At the same time, the Hallmark Art Collection continues its collecting activity in other media.

While corporate art collecting remains an often secretive activity, employees, customers, and guests at a company have the rewarding opportunity to see and be surrounded by original art. A company's art collection is a reflection of the company and can provide an outsider with a different viewpoint and perception of a corporation. Ultimately, a well-managed and well-cared for corporate

art collection not only enhances a workplace setting, it also supports the art community as a whole.

Corporate Information Centers

Barbara M. Spiegelman

Churchill Associates, Pittsburgh, Pennsylvania, U.S.A.

Nancy Flury Carlson

Westinghouse Electric Corporation, Pittsburgh, Pennsylvania, U.S.A.

Abstract

Information has become the lifeblood of the global economy. Corporate information centers (CICs), often called special libraries, leverage this force as they provide services to meet the specialized needs of a company, organization, or group. The CICs are typically staffed by library and information professionals, "...information resource experts dedicated to putting knowledge to work to attain the goals of their organizations." They provide information support to decision makers, researchers, and administrative and technical personnel.

INTRODUCTION

Information has become the lifeblood of the global economy. Corporate information centers (CICs), often called special libraries, leverage this force as they provide services to meet the specialized needs of a company, organization, or group. The CICs are typically staffed by library and information professionals, "...information resource experts dedicated to putting knowledge to work to attain the goals of their organizations."^[1] They provide information support to decision makers, researchers, and administrative and technical personnel.

A CIC provides both specialized services and a targeted collection of the information resources most needed by the organization's personnel. Since these people are generally inundated with information, do they really need the CIC? As Leigh Buchanan notes, "...the kudzulike spread of information—information that's readily accessible yet often inaccurate, confusing, and more than slightly irrelevant—has actually increased the need for librarians."^[2] The staff of the CIC helps to solve this problem. They review the world of resources available, and then identify those that are accurate and applicable to their organization.

SUBJECT AND SERVICE SPECIALIZATION

Subject Specialization

Because the corporate information center serves a unique clientele, the staff is able to build both subject and service specialties. Obviously, the subject specialty reflects the goals of the parent organization. For example, the library in a textile company will have information resources—both print and electronic—that relate to aspects of the textile industry. They will have resources that cover the

hard sciences, like chemistry as well as those on color, durability, and manufacturing processes.

How can we consider this textile company a specialized subject area, when it includes so many disciplines? The answer is that the information resources selected from these many disciplines all relate to textiles. Another way to look at it is to consider the disciplines that are not covered in this library. Do they have print materials related to music or resources in psychiatric medicine? Does the collection cover history and philosophy? Do they include general dictionaries or only dictionaries pertinent to the textile industry? Only resources related to the industry are included. The smaller world inside a larger universe is characteristic of a corporate information center. Fig. 1 pictures some of the areas in the Nike Design Library.

Service Specialization

Public libraries, which are funded by tax dollars, often assess their value by the size of their collections. These libraries are serving every citizen, providing content for every interest, and covering every subject imaginable. In this arena, collection is king.

The goal of the corporate information center, however, is to provide pinpoint access to exact information in the shortest time possible. In the language of corporations, the corporate information center is a key player in building competitive edge. The corporate information center client values its collection, but values its services more. Figs. 2 and 3 show work areas next to information areas at Deutsche Bank.

The focus on the organization's subject area enables the staff of the corporate information center to provide services that are unique, or at least tailored, to their customer base. A company's information center, for example, may provide an alerting (current awareness) service in a very narrow area for a small number of employees in a small department.

Fig. 1 Areas of the Nike Design Library.

Imagine the library in an information technology company that specializes in enterprise-wide networking. The end users have the skills and knowledge to manipulate any database in existence, but they do not have the time or

training to identify which commercial databases are the best for their specific information needs. As the information landscape of their industry changes, their corporate information center may identify new or different state of

Fig. 2 Book cabinets in a work area at Deutsche Bank allow easy access to information.

the art resources on a daily basis, and provide that information to the end users in the same tight time frame. In a large law firm, the corporate information center may provide an indexing service for depositions. In cases that include hundreds of thousands of documents, this service is worth its weight in gold to associate and partner alike. In these examples, the library provides a service that frees the end users to do what they do best. Figs. 4–10 show parts of the CIC at Deutsche Bank.

Are There Also More General CIC Services?

The CIC general services include reference, document delivery, research, electronic resource management, and internal information consulting. The collections of information include both external and internal materials. They may be traditional print collections such as books, journals and reports, or other specialized media; and objects such as images, material samples, or microscope slides. Collections may also be virtual, such as networked resources or databases. The corporate information center staff works with executives and managers to support decision making, strategic planning, and market research initiatives. They

Fig. 3 Employees share an alerting area at Deutsche Bank.

Fig. 4 A computer work area at Deutsche Bank.

work with technical personnel to support scientific research and development, engineering, and manufacturing. The CICs also provide industry data, benchmarking, statistics, and other information to support administrative personnel in the areas of human resources, financial planning, quality assurance, and public relations.

How Many Special Libraries Are There?

Statistics provided in The Bowker Annual, Library Trade and Book Almanac, 2000, indicate that there are 9691 special libraries in the United States. This figure includes corporate, medical, law, religious libraries, but not special libraries in public, academic, armed forces, or government libraries.

QUALIFICATIONS AND ONGOING PROFESSIONAL DEVELOPMENT

How Is the CIC Staffed? What Are the Staff Qualifications?

The range of staffing for a corporate information center can vary widely based on the role of the center, the demand for

Fig. 5 Storage units.

Fig. 6 Information storage.

its services, and the budget allocated to the function. The professional degree for this field is a master's degree, offered in the area of library or information science, and requiring one or two years of postgraduate education. Ongoing professional development is essential to ensure that the staff remains conversant with developing products and technology. The company itself, information vendors, and professional associations provide advanced training in the field. Depending on their needs, most experienced information professionals belong to the Special Libraries Association (SLA), American Society for Information Science (ASIS), the Medical Library Association (MLA), the American Association of Law Librarians (AALL), or other professional societies.

USERS AND SERVICES

Who Uses a CIC?

The intended user base of a corporate information center is typically defined by the CIC's mission statement or by its functional position in the organization. The CIC may serve

Fig. 7 A storage wall in the Information Center.

a narrow or broad constituency. In some cases, the CIC may be intended to serve only a subset of a company. For example, it may be a technical resource used only by research scientists within a larger corporation, or a business library serving only management and executive personnel. Alternatively, the CIC may serve an entire division, business unit, department, or other organizational segment. It may be chartered to serve the entire organization, or even to serve the external customers of an organization. As an example, a pharmaceutical company's CIC may support scientists, marketing, and administrative personnel, and may also provide some information services directly to consumers of the company's products.

What Services Are Provided by the CIC?

Because a corporate information center's service offerings vary widely according to its purpose within the organization, there is no set suite of services provided by all CICs. Major areas of service may include reference, research, current awareness, collection management, information resource management, document delivery, and information consulting.

Fig. 8 An employee at work.

Fig. 9 A specially designed information cabinet.

Reference

Reference service, in a nutshell, means answering questions. The questions answered through reference services may be simple lookups of facts, dates, names, addresses, or definitions. Many libraries define reference service to include primarily quick-turnaround, limited-scope, and relatively easy-to-answer questions. But sometimes reference questions may be complex, open-ended, and even unanswerable, and the staff's response can include a range of options for further pursuit of the question. In a corporate information center the reference service can be viewed as the cornerstone for all other services, because it measures the pulse of the organization's ongoing information needs. In the course of meeting these changing needs, the staff continues to develop its complement of internal and external resources. Needs identified through the reference process subsequently influence the CIC's planning and priority setting in collection development, service offerings, planning, and staffing.

Research

Research services include literature searching, primary research, and synthesis of information. A literature search is a comprehensive review of electronic and print information resources. The goal of the search is to compile a focused set of references or documents pertinent to a specific topic. Primary research extends beyond a review of written or published data, and involves the gathering, interpretation, and synthesis of

Fig. 10 A work area at Deutsche Bank.

information directly from people such as industry experts, researchers, or authors. Primary research is especially significant for supporting functions such as competitive intelligence or market research, which are unique to each company. Information synthesis and reporting are the refined end products of literature searches and primary research. Benchmarking of products or companies is an example of this process, in which literature searches and primary interviews are used to compile data and information. This information is studied, organized, and presented with comparisons, conclusions, or recommendations for action.

Current Awareness

The information center's current awareness services provide ongoing updates of targeted information to users interested in following a specific topic, company, or technology. Current awareness may be topic-specific, such as a monthly update of new developments in the telecommunications industry, or it may be resource-specific, such as a monthly table of contents from a specific journal title. Current awareness services may be compiled and distributed directly by the corporate information center staff or set up through external vendors.

Collection Management

Corporate information centers may manage collections of internal or external documents or information. The collections may be physical, as in a print book or journal collection, or virtual as in an electronic document management or intranet system. Examples of internal collections include patents, technical reports, policies and procedures, scientific data, or organizational records. External collections can include externally published books, journals, reports, conference proceedings, audiovisuals, and standards. A formal collection development policy or statement of scope often

drives collection management. These tools define the types of materials and topical areas collected, and they are useful in making decisions about how to allocate acquisitions resources to collect and organize the most important materials for the organization. Collection management includes acquisitions, cataloging, indexing, development of finding tools, and circulation. In addition to providing tools for users to locate collection materials, the corporate information center staff interacts directly with users to help them locate the specific materials or information they need.

Information Resource Management

An extension of collection management, information resource management includes the planning, purchase, implementation, and administration of intranets; content licensing, intranet subscription services; or other electronic or networked resources. Management of content licensing and intranet subscription services, in particular, enables the CIC to help control the cost of information access across the organization. Successful implementation of these services requires effective teaming between the CIC, information technology, communications, and purchasing. A teamwork approach ensures that there is less duplication of effort within the company, and less duplication of purchased resources.

Document Delivery

While a collection management effort strives to maintain key materials and frequently used documents in-house, there is always a need to quickly and cost effectively obtain materials from outside the organization. Document delivery services are designed to purchase or borrow books, photocopies, journal articles, and other resources from publishers, vendors, and other libraries. These services can be very effective in obtaining both print and electronic materials and provide good backup to the information center.

Information Consulting

Consulting services offered by the CIC may include information audits, information mapping, and project information support. Information audits can be used to identify an organization's information needs, gaps, and processes; they also serve as a basis for better information resource allocation, process improvement, and communication. Information mapping can be used to identify, document, and provide pointers to an organization's internal data and information resources, which would otherwise be underused or hidden. Project information support makes an information professional available to support new initiatives or task teams, and in many CICs it is standard practice to assign an information specialist to these teams as they begin their work. This staff member can provide

topical background information, ongoing current awareness, and research specific questions that come up in the course of the initiative.

IMPACT AND STRATEGIC POSITIONING

How Does the Corporate Information Center Impact the Organization?

In addition to its primary role of access to information, the CIC can introduce new technologies to the organization; research and highlight industry measures of total quality; perform needs assessments and information audits, facilitate focus groups and design surveys, and map information in the organization to identify critical resources. All of these roles rely on the CIC's strategic positioning within the organization.

A CIC must be flexible, responsive to change, and able to extend and tailor services to provide what the organization needs before the need actually arises. These organizational needs must continually be identified and verified through frequent communication and feedback with users and organizational leaders. If the information center has the best collection in the world on large widgets, but the company has changed its strategic direction to small widgets, that collection is of little use to the company.

What Are the Corporate Information Center's Costs and Benefits to an Organization?

In addition to providing the information needed to support organizational functions, CIC services can save both money and productive time. King Research, Inc., funded by a research grant from the Special Libraries Association, compiled data from 23 studies of special library users and services, and four national surveys of scientists, engineers, and other professionals. This study reported, "it would cost these parent organizations about 2.9 times more for their professionals to obtain information from other sources than it now costs to run the library."^[3] Savings of this kind are obviously important to all organizations that watch their bottom line.

Productive time is a "soft savings," that is, one that does not usually register on the company's balance sheet. One channel for loss of productive time is the inclination of a company's professional and technical employees to "surf the Net" for the information they need to do their jobs. "Most professionals with internet access on their desktop computers don't know the most efficient way to conduct a search. Further, employees are too often satisfied with finding any information on a subject—not necessarily the best data or most significant source. Top-notch librarians, however, know how to find primary sources and judge information. . . ."^[4]

Where Does a Corporate Information Center Fit Within Its Organization?

The CIC may report to information systems, human resources, records management, facilities, business planning, or a general corporate services function. The organizational placement of a corporate information center may define or reflect its overall purpose. Placement within information systems is appropriate for an organization in which the most valuable information resources are available chiefly through electronic means such as Internet, intranet, internal databases, or networking. This type of corporate information center is effective in an organization with an employee population skilled in using computer-based resources, and in an industry that relies chiefly on current rather than historical information.

A corporate information center placed within the human resources department is likely to be found in organizations that strongly associate access to information with employee development and organizational learning. A library in this setting may be expected to provide information resources to meet both the business and personal needs of employees. To support organizational learning, this library may be involved with knowledge management initiatives or other organization-wide projects to capture and redeploy employee expertise.

A CIC placed within an organization's records management setting may be more closely identified with the organization's internal information. This type of library can add value to the management of records and document management systems, especially by contributing its expertise in understanding the interface between people and information systems, and by putting into place tools to help people locate information more easily.

An information center placed within the business-planning segment indicates that the organization recognizes the value of information to the business and strategic planning function. A library in this setting is likely to provide services to management and executives, sometimes to the exclusion of the general employee population.

Finally, placement within the general services organization of a company indicates recognition that library services are needed by the organization as a whole, just as accounting and procurement may reside in this general services structure. This placement may free a library to design a wider range of services based on varied needs across the organization, but may also limit it by keeping it perennially in the crosshairs of ongoing hunts to control costs.

Is there an ideal setting for the corporate library or information center? Probably not, since placement depends on the needs of the organization, the perceptions of the company's decision makers, and the abilities of the CIC to prove that the resources and services it can provide are valuable. In reality, most corporate information

centers exhibit characteristics related to all of these settings. CICs continue to change and recreate themselves, including moving from one organizational reporting structure to another, as their companies themselves continue to restructure and reorganize to meet the changing business environments.

Budget

Budgets for corporate information centers typically include line items for personnel, information resources, and general costs. Personnel costs include the cost of employee benefits and training. Information resource costs include the costs of materials purchased centrally for any library collections or directly for the company employees, commercial database fees, and annual fees for internet subscriptions or networked electronic resources. General costs included in a library's budget may include internal services such as information technology support, reproduction, phone, workstation, and facilities costs. In general, corporate libraries must justify costs on an annual basis, at budget planning, and at approval time. They must gain the approval and support of the management of the library's primary user bases, who often share in the cost to retain the corporate information center.

Many libraries are funded through chargeback or assessment to these user groups each year, often on an overall basis linked to user and service statistics, or on a transactional basis throughout the year. It is easier for special libraries to justify their budgets if they consistently assess user needs, design services to meet these needs, and communicate their value.

One challenge to a library's budget activities is the rising cost of information resources. Journal subscription costs in particular, whether print or electronic, provide a good example of the difficulty of controlling costs. Journals that focus on a specific industry segment or scientific field often rise most dramatically in cost, but are also those most needed by companies that work in these specific industries or scientific areas. It is prudent for the manager of the information center to clearly delineate the cost of these expensive resources and the customers who use them the most often.

COMMUNICATIONS

Good communication is central to the success of a corporate information center. In a business setting, information is primarily used to make decisions and, therefore, must be shared, rather than added to a collection on a shelf. A variety of communication skills are used many times every day, and it is expected that professional staff will have these skills when they begin the job.

Advanced listening skills are an absolute requirement in this setting, since the staff will be required to interpret

the actual needs of the customer, rather than relying on the customer's knowledge. Customers from human resources (HR), for example, can be expected to know a great deal about HR, but may not be up to date about marketing. They may have heard a marketing information resource mentioned, and assume that since they are interested in marketing job positions, that same resource will work for them. The staff uses the reference interview process, including active listening, to identify the actual information that is needed.

The staff of the CIC is also required to be able to communicate effectively, in speech and in writing, to customers from the lowest to highest position in the organization. Communications with the manager of a technical department, for example, may include a quick précis of research techniques and technical jargon, which demonstrate that the librarian speaks his language. Communication with the chief executive officer (CEO), on the other hand, must be brief and well focused, as the CEO will probably have less time, and be more interested in bottom-line issues. In communications like this, the information specialist must take into consideration two points: what is the listener's past knowledge of the subject (are they familiar with the topic? are their perceptions based on misinformation?); and what information does the audience actually need to make a decision (statistics? anecdotal evidence? trends over time?) Keeping these ideas in the forefront will ensure that the communication is on point.

Does the prevalence of electronic messaging and e-mail indicate that written communication skills are no longer important in a corporate setting? The use of these vehicles actually makes clear and effective written communication more difficult. It is quite easy to take a wrong tone in an e-mail. Once that e-mail is delivered, the tone speaks for itself, with no in-person speaker to clarify the intent or modify the message. It is easy to eliminate the use of all capitals, which is effectively screaming at the customer, but not as easy to detect when a comment might be interpreted as sarcastic rather than as humorous. Careful editing is required for good writing, and is especially important for electronic communication.

The need for excellent communication skills becomes even more important with the growth of a global economy. Professional staff can no longer assume that every customer will speak American English. Requests for research or other services may come from foreign subsidiaries, customers from abroad, or from people who work in the same building who are not native speakers.

In a diversified corporate setting, it is easy to find yourself with a customer who is exceedingly difficult to understand, and who has trouble understanding in return. How can this problem be handled without insulting the customer? The first rule, of course, is not to speak louder, under the assumption that the problem is one of intelligence rather than of translation. In instances where the

customer is providing data, it is imperative that the staff ask the customer to write the information; in this way, numbers will not be misunderstood, which can lead to disastrous results!

STRATEGIC PLANNING

The corporate information center must align its goals and objectives with those of the parent organization and reflect these goals in its own strategic plan.

The term strategic plan sounds ominously complex, but it simply means outlining where the special library is going, and how it will get there. The plan identifies the goals and objectives of the library, and the actual steps required to reach them.

As an example, a company's five-year strategic plan calls for entering a new market, which will require that the whole company shift its focus toward a new material or process. To help the company achieve this goal, the CIC must allocate a portion of its budget to cover more resources to support this initiative, and to add or develop staff to specialize in those areas. In theory this is not difficult; it simply requires moving funds from one pot to another.

In practice, however, the company has many goals, and some seem to be in conflict with others. Imagine that in the example above, the director of Marketing requests the CIC to increase support to his department next year. How can library funds and staff be allocated in this situation? The answer can be found in the company's strategic plan, which prioritizes its various initiatives. If the company's strategic plan calls for increasing allocations to product development by 10%, over the previous year's allocation of 5%, the library must shift its focus to increase resources and services related to product development. The CIC's strategic plan is, therefore, based on the organization's upper tier plan. Each request for services or resources should be considered and balanced in light of the CIC's strategic plan. In this case, the additional 5% allocated to product development cannot be allocated to other needs. When other groups request library services to support their initiatives, the strategic plan provides the basis for the allocation decision, and the explanation to the unhappy marketing director, who may not see more research into customer attitudes.

BUILDING COMPETITIVE EDGE

Understanding Competitive Edge

In the for-profit sector, time to market is everything. Time to market is the difference between a profitable product and an unprofitable one. Time to market is money.

A good example of this concept lies in over-the-counter pharmaceuticals. Name an over-the-counter product that reduces fever quickly. Most of us will name the same one, because it was the first on the market to make that unique

or specific claim. Once a product has worked for them, the average consumer is likely to buy it again. Voila! This way lies profit.

How can the corporate information center help to improve time to market and, therefore, help the organization be increase profitability? One of the best ways to understand the corporate information center's role in building competitive edge is to imagine a Slinky, the creeping toy loved by children far and wide. The rings of the toy can be pulled apart, leaving wide spaces between the coiled wires, or they can be pushed together, so that the coils are all touching. The extended Slinky, with wide open spaces, represents the infinite amount of information that can be found on almost any topic. The contracted Slinky, with every ring tightly closed, represents the goal of the CIC—targeted information located in the shortest amount of time possible.

But in a real time-to-market scenario, the end user may not even have time to ask the library for help. Outstanding corporate information centers are successful because they proactively provide the right information before anyone thinks of asking for it. They understand the organization's goals, they know their subject matter, and they deliver unique service with a smile.

Customer Intimacy

Customer intimacy is increasingly important to companies doing business in the global economy. Ongoing globalization of industries causes upheaval, realignment, and repositioning of industry players. In many industries, a company may be competing fiercely with its competitors in some arenas, yet partnering with them in others. With lines between competitors blurring, the company—customer relationship becomes even more critical. Companies must not only be responsive to their customers in a reactive way, but also proactively anticipate customer needs and provide solutions to their problems. Communication and information are foundations of this relationship. Corporate information centers must create this same relationship with their customers through expertise, effective information services, participation in knowledge management and competitive intelligence initiatives, and effective teaming with key organizational functions.

Challenges for the Future

Corporations will continue to fight the battle of information overload. For every decision that is made, there is a need for information. Sometimes not too much information is needed, since the CEO is not writing a journal article. At other times, lots of information is needed for the people in the research department, who are. And most times, there is a need for every possible choice of volume or specificity in between. Information overload will remain a challenge for

the CIC. How can it continue to identify the absolutely relevant and accurate information, as the marketplace is continually flooded with everything else?

As the information industry continues to refine a pricing model, the CIC will be more strategic than ever, since it is the first line of defense against models that are too extreme. As pricing models change, CICs may need to change the way they budget and charge for services. Since budgets follow costs, that is, the next year's budget is based on this year's costs, considerable strategic planning skills will be needed to anticipate these changes. Those who are not able to anticipate accurately will find themselves lagging behind an entire budget cycle, which can affect the information center's ability to function.

Some corporations may see a centralized information center as an anachronism, since they view it as a place rather than a service. These organizations may want to employ information professionals in other venues, for example, in knowledge management, competitive intelligence, or market research functions. This change in the information professional's role will be both a challenge and an opportunity.

CONCLUSION

Finally, information vendors, including established publishers and brand-new entrants to the information markets,

are grappling amongst themselves for market share and role definition. As part of their response to this instability, some vendors are attempting to subsume the role of the corporate information center. In an attempt to maintain market share, they are trying to be all things to all organizations by providing outsourced services. Maintaining the role definition of the CIC will be crucial in meeting this challenge.

Notwithstanding these challenges, corporate information centers remain exciting and dynamic organizations. They are positioned to make a difference to their company and to the future of the profession.

Corporate Records Management

Barbara M. Cross

Records and Information Management, Sony Pictures Entertainment, Culver City, California, U.S.A.

Barbara E. Nye

Ictus Consulting, LLC, Pasadena, California, U.S.A.

Abstract

Records management is the discipline used by corporations to ensure management principles are systematically applied to the recorded information created, received, and used in the normal course of business operations. The corporate records management program uses established records management methods and practices to reduce costs associated with recordkeeping, provide efficient access to and retrieval of business information, help to protect information critical to the business, and overall bring recognized value to the corporation. Corporations deal with increasingly complex recordkeeping requirements due to the continued growth of electronic records as well as legal and compliance issues. Corporations face records management issues that government entities may not as they comply with international laws and regulations, civil litigation and the impact of electronic discovery, and mergers and acquisitions.

INTRODUCTION

Corporations are legal entities established to provide goods or services in order to make a profit. In addition to managing the core operations that make the goods or provide the services, corporations also employ various management techniques (disciplines) to more efficiently manage the business and to control the costs associated with doing business. Using financial management, human resources management and other related disciplines serve to make operations more effective and efficient, thus adding to profits, the so-called “bottom line.”

One of these management disciplines is records management—the systematic analysis and control of the creation, receipt, maintenance, use, and disposition of recorded information. Corporations establish records management programs (RMP) to manage all records (considered to be “information assets”) in all stored formats—paper-based, photographic, or digital storage. Employing records management techniques helps to lower the cost of doing business by controlling the growth of records maintained and by facilitating efficient access to recorded information needed for business decisions.

Corporations create, receive, and maintain a considerable amount of recorded information as they document what they intend to do (writing policies and plans) and how they intend to do it (developing procedures). As work activities are completed, corporations document the results of work activities, in the form of reports, meeting minutes, training presentations, photographs, charts, tabulated data, etc. The resulting recorded information must be properly managed to be of any benefit to the corporation.

The corporate RMP is responsible for managing the recorded information.

Records management activities help to make corporate operations more efficient by supporting both internal operations and by helping to meet external recordkeeping requirements and expectations.

Internal requirements include being accountable to an executive function or to a governing board, and if publicly traded, to shareholders. This is done in part by providing proof, in the form of records, that work activities were completed and completed correctly.

External requirements (in the form of laws or statutes) are those imposed by government legislative bodies or by government agencies (in the form of rules and regulations). Conducting business is a privilege, rather than a right.^[1] This privilege is conferred and controlled by one or more government agencies, and thus businesses often must comply with multiple requirements. These regulations often impose recordkeeping requirements on many business activities to make sure that there will be proof that the corporation complied with the appropriate requirement.

Corporations also operate within a larger social environment and the corporation may wish to present a positive image of the corporation to the public, establish good relations, or meet societal expectations as a “good corporate citizen.”^[2]

Records management supports the goals of cost savings and compliance by managing recorded information, regardless of the storage medium (paper, photographic, or electronic), from the time the records are created or received, until they are dispositioned. This concept of

“cradle-to-grave” management is called the records “life cycle” and is a fundamental tenet of the discipline.

Records management is also practiced in other types of organizations in addition to public and private enterprises. Government agencies at the local, state and national level, nonprofit organizations, universities and cultural institutions, all create and maintain records as one result of their operations.

The same principles of the record management discipline apply and many of the same methods are used. Records management in government agencies differs most significantly in the granting of access to many of the records maintained. The government agencies presume that outside parties (generally speaking, the public) have some rights to access government records, as the government conducts activities on behalf of its citizenry.

At the U.S. federal level the Freedom of Information Act (FOIA) codifies this right to access.^[3] States also grant similar rights to access records maintained by state and local agencies. In California, for example, the California Public Records Act, states that most records maintained are accessible by the public, delineates which records are not, and provides requirements for producing public records when requested.^[4]

Private and publicly traded companies do not have to comply with FOIA, and therefore, do not need to provide the public access to their records. Indeed, as records are considered a corporate asset, and often of a proprietary nature, corporations spend considerable effort protecting records and information from unauthorized access.

A comprehensive corporate RMP has five broad elements.^[5] These include:

- Records retention: determining how long to keep records.
- Compliance: ensuring that the corporation is aware of external recordkeeping requirements and complies with them.
- Active records management: arranging, organizing, and storing current or frequently referenced records to promote efficient retrieval and use.
- Inactive records management: identifying records that are no longer frequently used and transferring them out of an expensive office or work environment to low-cost warehouse storage or transferring them offline to tape or other cost-effective electronic storage.
- Vital records management: protecting records critical to support ongoing operations to ensure that they are available to respond to an emergency or disaster.

RECORDS RETENTION

As mentioned earlier, records retention is the activity of determining the value of a record to the corporation and assigning a timeframe (retention period) for maintaining it.

Records retention has been called “. . .the defining responsibility of records management as a business discipline.”^[5]

A key part of the corporate RMP is the “records retention schedule”—a list of each grouping or collection of records (called a “records series”), the time period the records series must be maintained (the retention period), and the assignment of business unit (e.g., department, division, section) responsible for the records series.

Records retention schedules can be developed using one of several methods and can be presented in several formats. The important point for purposes of this discussion is that the retention schedule is a policy document that states the corporation’s intent to maintain its records for certain time periods.

Determining the appropriate timeframe for keeping a records series involves analysis of the business (or “operating”) need to maintain the record and any pertinent legal requirements. These two considerations are applied to each record series in establishing the retention period. Once the records series meets the retention period, the records are either destroyed, or retained in an archive, if they have been identified as having historical significance.

This process of deciding how long to keep a record series is called “appraisal” as it involves determining the “value” of the records to the organization, and at what point the records no longer have value.

There is a risk management component to this decision-making process. There is a risk to both keeping the record indefinitely and to not keeping it. As records are created and maintained by organizations in order to support their position or to defend against allegations, deciding how long to keep records is very important.

The risk to maintain the record involves determining the cost of maintenance (physical storage space, equipment and supplies, as well as computer disk storage), personnel (to maintain files and ensure digital records are protected), and if the organization is involved in litigation or a government investigation or audit, the cost to find and retrieve relevant information.

The amount of risk in not maintaining a set of records indefinitely (in other words, putting a finite retention period in place) involves determining the costs that might be incurred if the organization decides after destroying the records that it now requires the information and has to recreate it, or if the records have been destroyed in error and are relevant to litigation or investigation, and therefore, should have been maintained.

Another aspect of risk management as a part of records management is the identification and protection of “vital records.” Vital records are those that contain information that is critical to ensuring the continued important operations of a corporation, and protecting its rights and assets, in the event of an emergency or a disaster. Frequently, the vital records are identified as such on the records retention schedule so that the business unit assigned responsibility

can ensure that they are protected and available to respond to the emergency or disaster. The records management function within the corporation works with the business recovery or disaster response function in planning for, and responding to, emergencies.

Records retention schedules must be customized specifically for a corporation. There are no “generic” records retention schedules that can be used as is. Although companies may produce many similar-type records, especially for those functions such as accounting or human resources management that all organizations have, the differences in industries, geographic locations, legal jurisdictions, and especially the corporate culture are all factors in determining how long the individual corporation is prepared to maintain records, or conversely at what point in time they are comfortable with the decision to destroy records deemed obsolete.

Legal Environment and Compliance

The legal environment in which a corporation does business influences all aspects of record keeping within the corporation. Laws and regulations can dictate the types of records an organization creates, the format in which records are kept, what access is permitted, how long the organization is obligated to retain records or how an organization may dispose of their records. Compliance with record keeping requirements helps companies avoid fines and penalties as well as reduces risks and liability during litigation, audits, or government investigations.

Corporations are governed by multiple and various jurisdictions. In the United States, companies are regulated by the states in which they incorporate, the federal government, and, if public, by the SEC. Local or regional jurisdictions may also regulate company actions. Multinational corporations have to abide by the laws and regulations of not only their “home” country but each country or territory in which they conduct business.

Key laws driving corporate compliance include anti-trust and competition laws, insider trading and securities laws, privacy and data protection laws, environmental and occupational health regulations, labor laws, and tax and revenue laws.

In addition, many industries have specific laws regulating their activities. For example, financial institutions are governed by legal controls regulating money laundering (Bank Secrecy Act) and the sharing and use of customer credit information (Fair Credit Reporting Act). Other highly regulated industries include health, energy, food, securities, and telecommunications.

Publicly traded companies follow rules and regulations laid out by the U.S. Securities & Exchange Commission (SEC). In response to the corporate finance and reporting scandals of the 1990s, the U.S. federal government passed the Sarbanes–Oxley Act of 2002 which applies to all publicly traded companies and which is

regulated by the SEC. The purpose of the Sarbanes–Oxley Act is to ensure the boards of directors of publicly held companies take responsibility for both receiving accurate information about the company’s finances and reporting accurately on those finances to the public.^[6] To demonstrate compliance, organizations develop internal guidelines, processes, reports, and other sorts of documentation that require appropriate management, retention and disposition.

U.S. laws cover not only business activities that take place within the country but also business conducted outside of the country. The U.S. Department of Justice oversees the Foreign Corrupt Practices Act (FCPA). The FCPA makes it unlawful to bribe foreign government officials to obtain or retain business. Signed into law in 1977, the FCPA requires publicly traded companies “. . .to maintain records that accurately and fairly represent the company’s transactions. . . . requires these companies to have adequate systems of internal accounting controls.”^[7] Anti-bribery provisions of the FCPA make it unlawful for a U.S. person to make a payment to a foreign official for the purpose of obtaining or retaining business for or with, or directing business to, any person.

Multinational corporations must take into consideration the laws and regulations of each country in which they conduct business. A U.S.-based records retention schedule cannot simply be applied to international offices as other country’s laws may contradict U.S. law. Efforts to apply a single retention period to common business records across countries may result in keeping records longer than necessary or not long enough, both costly to the organization in terms of legal risk and operational efficiencies.

For example, privacy regulations vary across countries and every company doing business that crosses borders must be aware of the regulations and laws pertaining to information privacy. The European Union (EU) has stringent rules governing how corporations can use, retain, and store personal data. The European Directive on Data Privacy of October, 1998, governs both how information is collected and retained within the European community as well as how that information may be transferred from the EU to other countries. Data can be transferred to countries outside of the EU if there is a guarantee of “adequate” protection. The U.S. Department of Commerce, with the European Commission, developed a “safe harbor” framework for U.S. companies to comply with the EU directive. Companies certified to the safe harbor are recognized by EU organizations as providing “adequate” privacy protection, as defined by the Directive.^[8]

How an organization meets its compliance obligations varies and usually multiple parties, including legal, finance, information technology, and records management are involved in corporate governance. Detailed knowledge of the organizations’ records as provided by the RMP plays a key role in corporate compliance programs.

Litigation, legal holds, and discovery

Business conflicts and disputes are part of the cost of doing business for corporations. Regardless of the type of products or services provided, every company is at risk of being involved in a legal action. Antitrust actions, workers compensation claims, breach of contract, product liability, and other claims and lawsuits share in common the importance and necessity of business information as material evidence to prove or disprove their case. Company records may support or be harmful to the company's position. The corporate RMP is a component of the company's larger preventive law strategy.^[9]

The RMP helps to reduce the legal risks facing an organization through the systematic retention and disposition of records. Retaining information that may be needed in defense of potential legal actions protects the organization while disposing of information no longer required by the company can reduce the risks and costs of legal discovery. Doing so systematically, in the normal course of business, protects the organization from accusations of deliberate destruction or arbitrary decision-making. Effective information management practices also protect the corporation during litigation. Well-organized physical, photographic, and digital records facilitate the identification, access, and retrieval of information that may be needed for a legal action.

In the event of, or in anticipation of, litigation, corporations have a duty to preserve relevant information. A legal hold or preservation notice is a common communication method used by corporations to ensure that records are not inadvertently or deliberately destroyed. The duty to preserve supersedes the records retention policies that mandate the destruction of records that have reached the assigned retention period. Depending upon the legal action, the duty to preserve information can be limited to specific records, individuals, and departments, or can cover all records across the entire enterprise. "The duty to preserve includes an obligation to identify, locate, and maintain information that is relevant to specific, predictable, and identifiable litigation."^[10]

RMP procedures describe the process for suspending normal records and information destruction (i.e., enforcing a "legal hold" on the destruction of obsolete records). Because legal holds are an exception to the records retention policy, when the need for the hold no longer exists, the legal hold is lifted. At that time, the corporation can return to "business as usual" in terms of records disposition, and process for destruction any records which have met the assigned retention periods.

Discovery is the fact-finding process that takes place after a lawsuit is filed and before the trial, in order to allow the parties in a case to prepare for settlement or trial.^[11] With the explosion in the amount of electronic information stored, the cost of electronic discovery, or "e-discovery," is significant.

In December 2006, amendments to the U.S. Federal Rules of Civil Procedure (FRCP) went into effect, which have a direct impact on how organizations respond to litigation and discovery requests. The amendments address the growing burden to organizations in terms of time, effort, and cost to respond to e-discovery requests during litigation. The FRCP amendments provide guidance for the handling of electronically stored information (ESI) during litigation. How organizations will address the impact of the guidelines remains to be seen as the risk of litigation and e-discovery is different for every organization.

ACTIVE RECORDS MANAGEMENT

Active records management involves the organization and retrieval of records that are referenced frequently within the organization to support specific business activities. Components include the methods used to organize active records, the documentation and processes supporting the methods, and the selection of appropriate housing or storage for the records. The purpose is to ensure that records are safe, available, and accessible when needed.

A filing system is the primary method used to organize active records. An organization can have both paper-based and computer-based filing systems. Filing system elements include file plans, procedures, and access controls. The file plan outlines the way the records are organized and is often closely linked to the records retention schedule. There are different types of filing arrangements which can be employed by the organization, both simple and complex, all of which are a variation on an alphabetic or numeric arrangement. Classification schemes are used within the file plan to group related materials together. Indexing techniques are employed to provide additional access points to the records. The corporate RMP brings standardization and uniformity to the methods used so that filing systems are consistent across the corporation yet flexible enough to accommodate different types of records, can provide the security and confidentiality required, and are maintained and updated regularly.

The housing of active records is important to the corporation for several reasons. One is to ensure ready access to, and quick retrieval of, the records most needed to conduct daily business. Second is to manage equipment costs and use office space in the most efficient manner available. A third reason is to make sure that vital and confidential records are safe and secure, protecting the organization from loss or unauthorized access.

Corporations select equipment that facilitates retrieval at the most efficient cost. Office space is expensive; minimizing the records equipment footprint is one way to keep costs down. This is done by selecting specialized equipment for the type of physical records being organized, such as using shelving designed to fit tapes rather than shelving for standard file folders.

The format of the record influences where it is housed and how it is accessed. Employing imaging systems to digitize paper records to make the records more readily available to employees is a common corporate practice. Records that are frequently accessed by multiple people across the organization are good candidates for imaging. Records management will play a role in the imaging program to help ensure that the imaging process is documented and meets standards, to determine if or for how long the paper records shall be kept after digitization, the levels of indexing required to aid in retrieval, appropriate security controls, and that retention rules are applied to the digitized records.

Document management systems are deployed to store and help manage digitized and electronic active records. Features such as check in/check out capabilities, version control, and flexible security models, provide greater control over electronic documents than simply housing the documents on a shared drive or an employee's computer drive.

Enterprise content management (ECM) systems provide the organization with the ability to manage all digital content, whether Web sites, images, documents, video files, audio files, photographs, or multimedia in one repository. ECM systems are attractive to corporations because they offer "one stop shopping" to solve a number of requirements for the management of digital content.

Electronic Records Management

The amount of information created and maintained in electronic format increases each year in volume and importance. Records management concepts and methodologies apply to all record formats, but there are special challenges in the management and control of machine readable or electronic records. A component of the overall RMP, electronic records management requires close partnership between the information technology and records management groups to ensure the rules are applied effectively to the data within the systems and applications.

One issue with managing electronic information is the sheer volume of records of which only a small portion may be official business records. Contributing to the volume is the ease with which duplicate information can proliferate. Although duplication occurs with physical (hardcopy) records, the issue is greatly magnified in electronic form. The same electronic record can reside on numerous employee hard drives, in shared drives, in e-mail systems, content and document management systems, stored on optical disk, be backed up to tape or other storage medium, and then be printed and eventually stored. The challenge is in managing all these copies, consistently applying retention, controlling access, and facilitating retrieval.

Just as with physical records, file arrangements, standard naming conventions, metadata, classification, and

taxonomy schemes improve access by providing systematic organization to the electronic information. For large stores of electronic information, the manual application of classification—human beings assigning records to categories—is labor-intensive and not economically feasible for organizations. Organizations may invest in search engines or automated classification tools to facilitate information retrieval.

The electronic record is dependent upon the hardware and software upon which it is created and therefore is vulnerable to factors such as system obsolescence, storage media instability, data migration, and potential data loss. The obsolescence of systems and applications may make long-term retention of electronic records impractical due to costs associated with the continued need to migrate data from one generation of software or system to the next.

Electronic Messaging

Electronic communication is the favored method of communication for corporate employees. The physical interoffice memorandum and carefully crafted letters to and from outside parties are a small percentage of corporate mail.

Electronic mail (e-mail) is an important method of communication and information transfer for corporations. The use of e-mail continues to grow each year. In 2005, the average user produced 75 e-mails per day; in 2008 that figure rose to 156 e-mails per day, according to the Radicati Group, a computer and technology market research firm.^[12] Using the figures provided by the Radicati Group, an organization with 5,000 employees is processing 780,000 e-mails per day. Managing all of this e-mail presents a major challenge to organizations.

Initially, corporations and professional records and information management organizations viewed e-mail messages as casual, transitory means of communication and not as records. Managing e-mail focused on limiting the volume of e-mail message stored due to the high cost of storage and hardware limitations associated with storing e-mails. However, it is now standard practice for corporations to treat any e-mail message as a potential record. As a record, the e-mail message needs to be managed systematically similar to other corporate records, according to business, regulatory and litigation requirements.

Corporations employ a variety of methods to manage e-mail. Methods include the imposition of quotas or mailbox size limitations; automatic deletion of user mailbox contents after a specified period of time; archiving systems that store e-mails declared a record by users; storage systems that store all e-mails created or received by an organization, removing the employee from the decision-making; and personal archives where the employee determines what e-mails should be archived and when, storing the archives on designated drives.

Instant messaging, voice over IP, and unified messaging are other electronic communication methods used by corporations. Unified messaging combines voice mail, faxes, and e-mails into one mailbox. This is attractive to organizations as it allows employees to access voice mail from the e-mail system and e-mail from the telephone. From a records management perspective, it represents more records to be managed and protected.

Electronic communications ultimately are managed depending on the regulatory climate, business needs, and organizational culture of the corporation. For example, financial industries are regulated by the SEC and the National Association of Securities Dealers and therefore may have stricter controls than a nonregulated business.

Electronic Records Management Systems

The technology of records management has evolved from systems supporting the organization and retrieval of paper-based records to focusing on the management of electronic records. The value of electronic records management systems (ERM) is in their ability to manage retention and disposition of physical and electronic records. As discussed earlier, the volume of electronic records makes a manual application of retention schedules much too labor-intensive and time-consuming to be economically viable. Automated means to track electronic records, apply disposition rules, and apply legal holds during litigation are important to the overall management of corporate records.

The electronic records management systems themselves must be accurate and trustworthy. Trustworthiness means that an information system, whether computer- or paper-based, is accountable and can produce reliable and authentic information and records.

According to the Gartner group, records management systems have become key components of content management systems.^[13] The records management software market has consolidated as large technology companies acquired smaller companies with stand-alone records management products. Now, many records management products are integrated into electronic content management systems (ECM) as part of an overall suite of products that may include Web content management, document management, and workflow. This integration can be beneficial to the corporation as they look for strong return on investment when purchasing technology solutions.

Since the late 1990s, the U.S. Department of Defense (DoD) records management standard, *DoD 5015.2-STD Design Criteria for Electronic Records Management Software Applications* (DoD 5015.2), has served as the industry benchmark for records management software standards.^[14] Although developed specifically for software vendors who want to sell their products to federal agencies, it is used by government and private companies alike. Compliance with the standard or obtaining DoD

5015.2 certification is a prerequisite for many companies when selecting records management software products.

The *Model Requirements for Management of Electronic Records* (MoReq) is a European standard for electronic records management systems developed for the European community. It is also used as a benchmarking tool for corporations looking to implement ERM systems.^[15]

INACTIVE RECORDS MANAGEMENT

Inactive records management involves the storage and protection of records that are no longer accessed on a frequent basis but are still necessary to the organization due to legal, audit, or other retention requirements. Ensuring the reliable retrieval of records when needed or to ensure appropriate disposal when obsolete is a key element of inactive records management strategy.

An inactive records storage program can achieve considerable cost savings per year by moving physical records out of expensive office space and into lower cost storage warehouses, achieving economies of space and equipment.

An element of inactive records management is to determine the most effective long-term storage mechanism. Determining whether to convert physical records to a micrographic or digital format for storage purposes will depend on the retention period, level of access expected, and cost-effectiveness. If the costs to store the records to the end of their life cycle are less than the cost to convert the paper to another format, then there is no reason to convert. Paper records that are stored due to space limitations with frequent access may be candidates for digitization. While the cost to store a container of records (usually a cubic-foot box) is low, the costs to retrieve, deliver, and refile boxes increase the overall cost of storage significantly. In this case, it may be cost-effective to digitize the records for access and retrieval purposes. Microfilm is a good technology for records that must be retained for a long time and are infrequently accessed. The small format requires less space than the paper records and so cost savings may be gained.

Organizations may elect to store and manage inactive records themselves or outsource the activities to vendors specializing in records storage (commercial records centers). If the latter, the role of the records management department is to manage the vendor relationship and ensure quality of service to the organization.

Corporations interested in preserving the history of their business may establish a corporate archive to provide evidence and information of their organization's functions, policies, procedures, origins, operations, products, and services. Corporate archives can incorporate documents, photographs, films, publications, and ephemera as well as objects that capture the history and development of

an organization. Preserving the records of company presidents and other policy-making offices can offer valuable insight into the reasons for corporate actions. Records management and archives may be fully integrated or separate functions that work closely together. The business archive complements records management by assuring the preservation of documents of long-term management, legal, fiscal, communications, and marketing value.

VITAL RECORDS

A vital record is any recorded information that is identified as essential for the continuation or survival of the organization if a disaster strikes.^[16] A vital records protection program is a key component of a corporate RMP with the purpose of ensuring the organization identifies and protects those records critical to the organization in the event of disaster. Vital records protection is often integrated into the corporation's overall business continuity or disaster recovery program. This ensures the information critical to the business is identified, protected, and available when disaster strikes.

Determining whether a record is vital is done through an appraisal process, typically as part of the development of the record retention schedule. The cost of protecting the records must always be weighed against the cost of reconstructing them and to other direct monetary losses, such as revenue, assets, and productivity if the records are destroyed prematurely. The point is to protect the information contained in the records rather than the records themselves, although the evidential value of the record is also considered and should be protected if necessary.^[17]

In addition to identifying the vital records, the program determines the method of protection. Disasters can come in many forms and with varying degrees of severity. There are natural hazards such as fire, water, mildew, light, dust, insects, rodents, and acids; human hazards such as theft, loss, unauthorized access; and disasters such as earthquakes, hurricanes, and explosions. Likewise, the methods of protection can vary. An assessment to identify the types of disaster an organization might incur must be considered when determining protection needs.

The vital records program is a form of insurance for the corporation, making certain that the information needed to respond to an emergency is available. It is therefore important that the type of disaster be weighed against the likelihood of these disasters, and the consequences to the organization if they occur. Methods of protection are dependent upon the type of disaster and level of severity. Three accepted methods of protection are

- Duplication and dispersal.
- On-site storage and vaulting.
- Remote storage and vaulting.

Operating procedures cover the use of records in daily activities, in emergencies, and after disasters. A vital records master list provides the organization with a complete list of all vital records, the business group responsible for protecting the records, the method of protection, the importance of the record, and frequency of taking protective measures.

MERGERS, ACQUISITIONS, AND DIVESTITURES

When a corporation decides to merge with or acquire another company, the motivation may be to reduce competition, diversify, or revive a business. Merging companies face enormous challenges as the successful integration of information, technology, equipment, and corporate culture is critical to meeting the business objectives driving the consolidation.

The role of records management in a merger or acquisition is multifaceted. Records management will provide support and assist in the overall integration of information assets, including records and data collections (physical and electronic) and systems. For certain industries, such as healthcare and finance, there are state and federal regulations to be considered regarding the management of information during a merger.

If both entities have established RMPs, then the integration of records management functions requires review and analysis. Issues to consider include whether to change record retention periods (a potentially huge and costly undertaking for large mergers), whether to incorporate the acquired organization's retention schedule or leave separate schedules, whether to integrate records management databases and systems, identifying staffing requirements, services offered, and whether to consolidate inactive records storage.

A third facet involves managing the records created during the merger itself. This includes due diligence records, contracts, and financial records among others. The due diligence phase of an acquisition is when the organization is still determining whether the deal is beneficial to both parties. Due diligence is information-intensive and very dependent upon data, documents and evidentiary records. It is also highly confidential and in many cases the records management group will not be involved until this phase is over and the records are no longer restricted.

When a company sells off a part of the business or a joint venture between organizations ends, there are very similar records management considerations. Instead of dealing with how information assets and systems will be integrated, now the questions involve how to deal with the records of, and related to, the departing organization. The legal obligations and liabilities of the organization will help to determine the proper division or sharing of information assets. The fact that a business unit or business

asset is transferred to a new owner does not exempt the original owner from responsibility nor from the need to retain the records associated with the unit or asset as required by law.

Dissolution of a company does not end its obligations to retain records. Statutes of limitations apply and the corporation can still be exposed to lawsuits. The Corporate Secretary is usually responsible for the books and records including following legal requirements for the retention of information after the dissolution.

Most relevant to the records management discussion is that ownership of the records and recordkeeping responsibilities are clearly defined and documented.

RECORDS MANAGEMENT PLACEMENT WITHIN THE CORPORATION

The records management function provides services across the corporation, supporting all departments, and working closely with other corporate support departments such as audit, finance, information technology, human resources, legal, risk management, security, and tax. Its placement in the corporation varies and depends on many different factors, including size and type of organization, management structure, organizational culture, and regulatory environment. The one constant is that there is no single place in the corporation where records management always lives.

Traditionally, it was common to find records management placed within the administrative services or operations area of the organization. The records management function was considered a “back office” operation and the perception of records managers as clerical staff (file clerks) rather than information professionals persisted for many years. More recently, due to the proliferation of electronic information and increased regulatory environment, the records management function may be placed within the information technology, audit or legal/compliance departments.

The challenge is that regardless of the placement within the corporation, records management is a non-revenue generating function. Records personnel must build collaborative relationships with key corporate support departments as well as direct relationships with the lines of business in order to implement, maintain, and grow the corporate RMP.

STANDARDS

Standards provide a means for which corporations can measure a service or a product against a set of guidelines. There are many standards incorporated into the workplace, several of which relate to records and information management. Not all corporations follow all standards;

rather corporations follow standards that best support their business activities.

The International Standards Organization (ISO), issues standards covering a wide variety of subjects; standards issued by this body carry an authority that comes with obtaining consensus from many countries. ISO 15489:2001 is the international standard on records management.^[18] Praised by the records management profession upon its release, it has the potential to serve as the model for RMP regardless of industries or geographic location. The U.S. National Archives and Records Administration based its approach to records management on the standard. ISO 15489 is a voluntary standard, so compliance is a business decision each organization makes depending upon their needs. This makes it difficult to measure the impact of the standard on corporate RMP.

The ISO 9000 Quality Assurance series of standards cover quality management systems in the manufacturing and service industries. Being compliant with the standards is important for certain industries—certification is required in order to do business in Europe for the manufacturers of telecommunications equipment and medical equipment. Other corporations may use the standards as a benchmarking tool without going through the accreditation process, which can be costly. Although not a “records management” standard per se, there are many records requirements in the standards. The activities that comprise the field of records management form the foundation for successful compliance with the records requirements of the standards.^[19]

RECORDS MANAGEMENT AUDIT

By law, publicly traded corporations must submit to external audits for verification that their financial records and statements are accurate and the company has fairly reported its financial condition. Corporations also conduct internal audits, carried out by employees of the corporation, to evaluate financial and operational controls over processes, records, and systems. The internal audit group usually reports back to a corporate audit committee or governance board with authority to enforce change. Information audits can be conducted against the RMP or be used to gauge employee and organizational compliance with the RMP.

Audits may be conducted by an internal audit group or outside consultants. Regardless, the audit should be an independent and objective review of the RMP with clearly defined standards so that the purpose, scope and measures of success are agreed to by all parties. Factors such as company size, geographic location(s), and workloads may impact the scope of the audit, dictating whether the audit covers the entire organization, focuses on a single business unit, or covers only a sample of records created since the last audit.

The RMP audit may be used to measure how well the records management function is serving the corporation; assess whether the corporation is in compliance with the RMP policies, procedures and processes; or identify gaps and areas of improvement with the organization and the RMP. It may be used as a method of benchmarking the RMP so that future reviews of the program are measured against the initial audit. The audit findings can serve as a roadmap for the RMP and provide a link back to the overall strategic goals of the corporation.

CONCLUSION

The purpose of a corporate RMP is to support the overall goals and objectives of the corporation. The program achieves this by bringing recordkeeping efficiencies into the organization, controlling costs associated with recordkeeping, and ensuring that information is readily available to support business functions. While the specifics of a program vary depending on a number of factors discussed in this entry, a comprehensive RMP includes the core elements of record retention, compliance, active records management, inactive records management, and vital records management.

By retaining only those records required for legal, regulatory, and business need, the company can reduce storage costs, improve access and retrieval, and reduce time and effort to reconstruct information in the event of disaster. Compliance with the laws and regulations governing records helps companies avoid fines and penalties as well as reduces risks and liability during litigation and audits.

Although records management practices were initially developed to better manage records within the U.S. federal government, businesses long ago recognized the value of these practices and began adapting them to the corporate environment.^[20] Corporate records management practices continue to evolve to better support the corporation by adopting appropriate technologies, by monitoring and responding to new and changing legal and regulatory requirements, and by evaluating the impact of these changes on information management.

Credibility and Cognitive Authority of Information

Soo Young Rieh

School of Information, University of Michigan, Ann Arbor, Michigan, U.S.A.

Abstract

This entry defines the concepts of information credibility and cognitive authority, introduces the key terms and dimensions of each, and discusses major theoretical frameworks tested and proposed in library and information science (LIS) and related fields. It also lays out the fundamental notions of credibility and cognitive authority in historical contexts to trace the evolution of the understanding and enhancement of the two concepts. This entry contends that the assessment of information credibility and cognitive authority is a ubiquitous human activity given that people constantly make decisions and selections based on values of information in a variety of information seeking and use contexts. It further contends that information credibility and cognitive authority assessment can be seen as an ongoing and iterative process rather than a discrete information evaluation event. The judgments made in assessment processes are highly subjective given their dependence on individuals' accumulated beliefs, existing knowledge, and prior experiences. The conclusion of this entry suggests the need for more research by emphasizing the contributions that credibility and cognitive authority research can make to the field of LIS.

INTRODUCTION

This entry traces the evolution of the concepts of credibility and cognitive authority in library and information science (LIS) and other related fields including communication, human-computer interaction, and psychology. It provides definitions for information credibility and cognitive authority. It also introduces multiple dimensions as well as theoretical frameworks explaining the process of assessing credibility and cognitive authority, concluding by discussing the significance of the two concepts and calling for further research in the area.

Historically, credibility and cognitive authority of information were considered as criteria for making relevance judgments in LIS. Due to the recent growth of the Internet and concomitant evolution of information, communication, and publishing mechanisms, LIS researchers and practitioners have increasingly recognized the importance of understanding credibility and cognitive authority as a research agenda in its own right. Today people have access to a wider range of information resources than ever before, and as a result, face greater challenges in evaluating the usefulness of information with which they interact. Given the popularity of various self-published resources in which the source of information is vague and uncertain, the assessment of information credibility and cognitive authority has become a ubiquitous human activity.

In this entry, credibility and cognitive authority are considered as closely related yet different concepts. Most definitions of credibility revolve around the concept of believability of information.^[1] This entry uses the term *cognitive authority*, coined by Patrick Wilson to differentiate it from administrative authority.^[2] Unlike a person in

administrative authority, the world's leading authority in a domain area has no power to command. Experts perceived as not only credible or worthy of belief but also influential in other people's thinking are termed cognitive authorities. Those people or information sources considered to be credible serve as the potential pool of cognitive authorities. That is, cognitive authority is one of the principal aspects of information credibility.

CREDIBILITY DEFINITIONS AND ORIGINS

Definitions

Credibility is an intuitive and complex concept.^[3] Rather than having one clear definition, credibility has been defined along with dozens of other related concepts such as believability, trustworthiness, fairness, accuracy, trustfulness, factuality, completeness, precision, freedom from bias, objectivity, depth, and informativeness. Most credibility researchers agree that credibility assessment results from simultaneously evaluating multiple dimensions. Among these, two key dimensions are identified: trustworthiness and expertise.^[4] Trustworthiness is a core dimension in credibility assessment that captures the perceived goodness and morality of the source.^[5] The perception that a source is fair, unbiased, and truthful contributes to the trustworthiness of information. Trustworthiness is, however, not a synonym for credibility because people also must recognize expertise in order to deem information credible. Expertise reflects perceived knowledge, skill, and experience of the source.^[5] Expertise is likewise an important factor given its close relationship to people's

perceptions of a source's ability to provide information that is both accurate and valid.

Trustworthiness and expertise are not always perceived together. An expert with the title of doctor or professor might have a reputation of being knowledgeable in a certain area but still might not be considered trustworthy for the tendency to unreliability or bias. A person may think of a friend as being honest and trustworthy in general, but the advice that the friend gives is not necessarily considered credible for the friend's lack of expertise. The most credible information is found in those perceived to have high levels of trustworthiness and expertise.

Credibility does not reside in an information object, source, or person, although the characteristics of the foregoing can serve as the bases for people's assessment. It is people who ultimately make judgments of information credibility. People who have their own experience, knowledge, and beliefs are likely to make their own credibility judgments. Many studies show, in fact, that judgments of credibility are highly subjective assessment processes. In this entry, credibility is defined as people's assessment of whether information is trustworthy based on their own expertise and knowledge.

Historical Development

The fields of communication and LIS are both concerned with the credibility assessment of information and sources. Credibility research, however, has evolved in fundamentally different ways, with each field having its own origins, approaches, and goals for the study of credibility over the past five decades. Some researchers believe that scholarly interest in credibility dates back to Aristotle's examination of *ethos* (appeal based on character), *pathos* (appeal based on emotion), and *logos* (appeal based on logic or reason).^[6] Aristotle's notion of credibility focused mainly on the characteristics of *ethos*, which is "the communicator's ability to inspire confidence and belief in what was being said" (pp. 422–423).^[3]

Scholarly examination of credibility began in the twentieth century when psychologists investigated persuasion as a part of the propaganda efforts during the World Wars. A series of landmark studies were conducted by the Yale Group which defined credibility as a receiver-based construct and suggested that credibility is determined by an audience's acceptance of a speaker.^[4] In the 1950s, mass media professionals took an interest in the notion of credibility when television became popular and subscription rates for newspapers began to decline. Professional news organizations' examination of perceived credibility of newspapers versus television then grew into the study of *media credibility* which to this day remains an established research area in the field of communication.

Credibility research began much more recently in LIS as compared to the communication field. This does not mean that LIS researchers and practitioners had no concerns

about credibility assessment in the past. Rather, LIS research into human judgments of information centered on the notion of relevance. Relevance is often seen as playing a significant, underlying, and yet elusive role for various information activities such as acquiring, organizing, storing, preserving, searching, communicating, interacting with, and using information.^[7] The history of relevance started with the first libraries as library users were concerned about the problem of finding information *relevant* to them.^[7] However, the notion of relevance remained hidden and implicit until Vickery's presentations at the 1958 International Conference on Scientific Information.^[8] Since then, relevance has been studied extensively in terms of frameworks for defining relevance dimensions, forms of document representation affecting relevance judgment, subjectivity of relevance judgment, and identification of criteria adopted by users in judging relevance.

While the majority of relevance research has discussed relevance in terms of its topical aspect, which concerns itself with whether or not the topic of a search query matches the topic of a document, alternative notions have been suggested. For instance, utility, which is entirely subjective and based on personal judgment, is proposed as a measure of information retrieval effectiveness.^[9] Relevance and utility are not the same concepts. Until the 1980s, relevance was viewed as judgments concerned with aboutness, pertinence, or topical-relatedness. Utility was considered a broad concept involving not only topic-relatedness but also quality, novelty, importance, credibility, and other evaluations. In the 1990s, a substantial body of empirical studies on relevance criteria was conducted, producing studies which consistently revealed that people use much more diverse criteria than mere topicality in making relevance judgments. The criteria identified in these user-centered relevance studies include credibility, authority, completeness, depth, currency, accuracy, quality, effectiveness, belief, and clarity.^[10]

In LIS, as in other related fields, the emergence and proliferation of information technology, the Internet in particular, provided the impetus for improved and more formal understanding of the notion of credibility. Empirical studies showed that people became more concerned about quality, credibility, and authority of information as they gain awareness of the fact that the Web lacks quality control mechanisms in contrast to traditional information retrieval systems.^[11] Further, when looking for information, people rely on multiple information resources and may even seek to verify across different resources given the availability and accessibility of various types of digital media and forms of information.^[12] The two fields—LIS and communication—that have studied credibility from different perspectives and presumptions because of historical origins have drawn closer together than ever before as both fields have paid more attention to the significance of studying credibility and authority assessment in the contemporary digital information landscape.

TPOLOGY OF CREDIBILITY

Communication researchers have traditionally drawn distinctions between source credibility, message credibility, and media credibility. *Source credibility* usually refers to “judgments made by a perceiver concerning the believability of a communicator” (pp. 130–131).^[13] Numerous empirical studies have investigated the dimensions of source credibility from the perspectives of message recipients and identified those factors that might influence audience perceptions of trustworthiness and expertise. These factors include dynamism, composure, sociability, qualification, reliability, animation, poise, and good-naturedness.^[14] A meta-analysis of 114 credibility studies revealed that source expertise is a stronger influence on persuasion than other source characteristics given that the expertise dimension of source credibility is more objective than other dimensions and consequently easier to assess.^[15]

Message credibility examines how message characteristics such as content, structure, language, and presentation can impact perceptions of the believability of information. But the distinction between message credibility and source credibility is not always clear. Credible sources are likely to produce credible messages, and credible messages are likely to be seen as originating from credible sources. When people have strong interest and involvement, message characteristics become more influential than source characteristics because they are motivated to scrutinize message content. In some situations in which little information is available about the source of a message, people tend to turn to message cues in making credibility judgments.^[16] Researchers have examined the influence of various factors such as message comprehensibility, number of arguments, incentives, fear appeals, one-sided versus two-sided messages, repetition, and presentation style on people’s message credibility assessments.^[14]

Media credibility focuses on the relative credibility of various media channels through which a message is sent. Media credibility studies typically ask which medium people would believe if they received conflicting reports on the same news story from different media such as radio, television, magazines, and newspapers.^[17] This question aimed to discover people’s perceptions of the relative credibility of different news media. Previous studies suggest that media credibility is strongly related to the frequency with which people use a particular medium. In them, people judge their preferred medium as being the most credible.

In recent years, media credibility studies have attempted to compare people’s perceptions of traditionally-delivered information sources (newspapers, magazines, brochures, etc.) and their online counterparts (online newspapers, online news magazines, online political Web sites, etc.). The popularity and unique characteristics of the Web as a medium led to studying *Web credibility* as a distinct notion. Credibility researchers

have proceeded to note the following characteristics of the Web: lack of filtering mechanisms, form inclusive of interaction techniques and interface attributes, source ambiguity, and infancy as a medium.^[18]

Computer credibility impacts the field of human-computer interaction (HCI) when computers act as knowledge repositories, instruct users, report measures, report on work performance, report on their own state, run simulations, and help in the rendering of virtual environments. Computer credibility assessment relies on simultaneous evaluation of four types of credibility: presumed credibility, reputed credibility, surface credibility, and experienced credibility.^[11] *Presumed credibility* refers to the extent to which people believe information because of general assumptions in their mind. Sometimes people make assumptions based on stereotypes rather than on truth, and these assumptions and stereotypes all contribute to credibility perceptions. *Reputed credibility* describes the extent to which people believe information because of what third parties—other people, media, or institutions—have reported. These reports may come in the form of endorsements, awards, or referrals. *Surface credibility* derives from simple inspection. People make credibility judgments based on first impressions of surface traits such as of book covers, the visual designs of software, interface designs, and the information architecture of Web sites. *Experienced credibility* refers to the extent to which people believe information based on their first-hand experience. It may prove to be the most powerful form of credibility because it derives from people’s interaction with others or with systems over an extended period of time.

Some credibility researchers who consider the processes of social endorsement to be crucial in credibility construction have proposed several variants of credibility including conferred credibility, tabulated credibility, and emergent credibility.^[6] *Conferred credibility* indicates that people sometimes recognize credibility not based on a real source of information but on other sources’ positive reputation, all of which helps alleviate skepticism. For instance, Google might confer its credibility on sponsored links in the search results page because most people are unaware of the sponsorship model and consider such links equivalent to Google’s results. *Tabulated credibility* refers to the assessments people make based on peer ratings of an individual, organization, or product. The availability of aggregated ratings from other people may widen the range of social input on which people can rely in judging credibility. *Emergent credibility* arises from a pool of resources, such as Wikipedia, wikis, social networking sites, and other applications created by individuals. These forms of credibility suggest that people are not isolated evaluators of credibility as well as that social engagements and interactions must be considered in understanding credibility construction and assessment.

AUTHORITY

Authority has been defined and discussed in many different forms across numerous disciplines, including philosophy, education, psychology, political science, law, religion, and LIS. Authority is related to those areas of competence or applicability over which it is exercised. Having authority is different from being an expert because authority is a relationship involving at least two people. A person can be an expert even though others may not realize or recognize the fact. No individual by himself or herself can be an authority. All authority is “a relation among a bearer, a subject, a field, in virtue of a particular quality, attribute, and context” ^[19], p. 77]. In other words, authority is limited to spheres. A person can speak with authority within one sphere, but with no authority on questions outside that sphere.

Many researchers agree on the two broad categories of authority: epistemic authority and deontic authority. The former corresponds to being an authority and the latter to being in authority.^[19] As an example of epistemic authority, when people say, “He is an authority on Hegel,” they mean that he is superior to others within a field in light of knowledge about Hegel. Deontic authority takes the forms of imperial authority as exercised by a state through its government and its various organs, paternalistic authority as exercised by parents over their children, and operative authority as vested in any designated leader or office. In place of epistemic authority and deontic authority, cognitive authority and administrative authority can be used as alternative terms in distinguishing more clearly these two different types of authority.^[2]

COGNITIVE AUTHORITY

Definitions

Cognitive authority is a kind of influence.^[2] Those who are cognitive authorities profoundly influence others’ thoughts. People who are not cognitive authorities may still exert an influence in the world. What distinguishes people who are cognitive authorities from those who are not is that the formers’ influence is recognized in some official manner. Cognitive authority is a matter of degree; thus the weight that a cognitive authority’s words carry for others might vary. Even though it is possible for an absolute cognitive authority in a given sphere to have an answer to virtually all of the questions within the area, people in general tend to take the opinions and advice of others with different degrees of seriousness. Cognitive authorities are those people whose opinions and advice are taken more seriously with more weight being placed on their words than on the words of others.^[2]

Two bases for cognitive authority need to be recognized: being an expert and being reputable.^[2] To qualify

as an expert, a person should show evidence of knowledge, skill, experience, training, and education. Because knowledge and skill are difficult to test directly, evidence in terms of occupational roles or advanced degrees often must provide support for claims to expert status. However, not all experts necessarily possess outstanding competence. Experience and education may provide evidence of basic qualifications but still be insufficient in providing a high degree of expertise. To be an outstanding expert, a person must have a reputation for that expertise. In addition, established cognitive authorities can transfer authority to other people. When reputation among peers is unknown, special groups of people already considered to be knowledgeable can be turned to. For instance, individual A believes individual B because individual A believes group C, and group C says that individual B can be believed. This rule—that one can trust those who are trusted by those one trusts^[2]—constitutes a central feature of cognitive authority.

Bases for Assessing Cognitive Authority

When people acquire influence from cognitive authorities, there should be an answer for the question “What makes you think so?” Whatever the reasons for thinking that certain others deserve cognitive authority, it is not for the reason that people always directly test the authorities’ knowledge. Rather, people often cite indirect tests that serve as the bases of cognitive authority judgments. Not only individuals are recognized as cognitive authorities: books, journals, newspapers, manuscripts, and films are all possible sources of knowledge and opinion though they give rise to the same kind of questions about cognitive authority: which works can be taken seriously?; how much weight can be given to what the texts say? When people have sufficient knowledge of certain topics, they can claim directly against what they already know. However, most texts discuss topics people do not know enough about to apply the direct test. This is because people look for information and consult texts to find what they do not know.^[20] Therefore, people apply various indirect tests for recognizing the cognitive authority of a text, including personal authority, institutional authority, textual type authority, and intrinsic plausibility.^[2]

The first apparent basis for recognizing a text’s cognitive authority is the cognitive authority of its author. People will trust a text written by an individual or group of individuals whom they trust. The tests of personal cognitive authority are based on present reputation and accomplishments. Recognition of personal authority does not automatically transfer to past or future work. An established reputation is insufficient to establish the current authority of old texts.

Another kind of test is associated with the publisher and publication history. A publishing house can acquire a kind of cognitive authority if it is considered to be good at

publishing high-quality work. Thus, publications by a publishing house people respect constitute a kind of personal recommendation. A journal can exert authority, too, which transfers to the articles it publishes. Other institutional endorsements are also used as tests of authority. For instance, sponsorship by a learned society or a professional organization serve as the basis of institutional authority, as could publication by a government agency. Then again, published reviews furnish a special indirect test. If a reviewer has cognitive authority then his or her review itself constitutes a personal recommendation.

The third kind of test, that of text type, is based on the text itself separate from its author or publisher. For instance, reference works such as dictionaries and encyclopedias do not draw attention to their compilers as people often do not know who the authors or editors are. Standard reference works tend to be revised frequently and may be considered as institutions in their own right.

Finally, the test of intrinsic plausibility is always available. Reading a few words or sentences of the text may be sufficient for people to decide whether or not to continue reading the entire text. Such rapid assessment is not entirely based on intrinsic plausibility, but does constitute a major part. If people find that a work represents a school of thought they reject or has a style of research they think worthless, they become discouraged from continuing to read the work. Although people do not always reject what they see as being in conflict with their prior beliefs and cognitive positions, they cannot avoid assessing the text's contents as plausible or implausible and accordingly bestowing or withholding cognitive authority.

THE PROCESS OF ASSESSING CREDIBILITY AND COGNITIVE AUTHORITY

Several theoretical frameworks suggest that the assessment of credibility and cognitive authority needs to be understood as a process rather than a discrete evaluative event. Most of these frameworks and models are developed in the context of Internet use and Web searching. Rieh's Model of Judgment of Information Quality and Cognitive Authority was proposed based on an empirical study conducted in the context of Web searching.^[11] Her model captures the point at which people make predictive judgments about which Web site contains credible information and then follows through to include evaluative judgments by which they express preferences for information encountered. When people open a Web browser, they take the first action based on a predictive judgment that must be made before a new page is introduced. The selection of a certain Web site is based on people's knowledge and experience, recommendations from others, or other characteristics of information objects or sources. Once people open a new Web page, they make an evaluative judgment in terms of how good the information is, how useful the information is, how

trustworthy the information is, how accurate the information is, and so on. The reasons underlying such judgments are based on certain characteristics of information objects and sources. If people find that evaluative judgments of the information do not match the expectations of the earlier predictive judgments, they might return to a previous page or decide to start with a new page. By iterating the process, people can reach a point at which their predictive judgments and evaluative judgments match and they will proceed to use that information.^[21]

Wathen and Burkell's model of credibility assessment, developed by synthesizing the literature in the field, also proposes that the assessment of credibility of online information is iterative.^[22] Upon entering a Web site on the first level of evaluation, people rate the credibility of the medium in question based on surface characteristics such as appearance, interface design, download speed, interactivity, and organization of information. Once the site passes people's credibility criteria in the initial evaluation, they then move to the next level of evaluation. Should the site fail the first evaluation, people are likely to leave the site to seek others. On the second level of evaluation, people consider the credibility of the source and the message, evaluating source expertise, competence, trustworthiness, and credentials. The message is evaluated in terms of content, relevance, currency, accuracy, and tailoring. On the third level of the evaluative process, the interaction of message presentation and content can be assessed with respect to people's cognitive states. Wathen and Burkell point out that, given the limitless number of possible interactions among contextual and intervening variables, credibility assessment becomes quite complex and difficult to predict.

Fogg's Prominence-Interpretation Theory grew out of a series of research projects conducted at the Stanford Web Credibility Research Lab.^[23] Fogg's theory describes the credibility assessment process from the point at which people notice something of interest in a Web site to the point at which they make their judgment. This theory states that two events need to occur for people to make credibility assessments on the Web: they notice element(s) in a Web site (prominence), and make judgments about what has been noticed (interpretation). If people do not notice the element, it would not have any impact on their credibility assessment of the site. Fogg's theory proposed five factors affecting prominence: involvement (motivation and ability to scrutinize Web site content), topic of the Web site, task of the user, experience of the user, and individual differences in users. Interpretation, the theory's second component, involves people's judgments about a Web site element in terms of being good or bad. Various factors relate to interpretation, including assumptions (culture, past experiences, heuristics, etc.), skills/knowledge (level of competency in the site's subject matter), and context (environment, expectations, situational norms, etc.). This process of prominence and interpretation can occur more than once because new aspects of the site can

be continually noted and interpreted in the process of making credibility assessments on the Web.

A number of credibility researchers have observed that people do not always engage fully in the cognitive effort of making analytical judgments of content messages and sources. Rather, people often rely on mental shortcuts to judgmental rules (or heuristics), which have evolved as generalizations in their knowledge base and have thus been refined through the course of their experience.^[24] People are often unaware of the role of heuristics in influencing their judgments, which can result in their accepting a message as credible without first attributing the specific reasons for their acceptance. Cues that trigger heuristics can either be embedded in a message or internally located within people's cognition.^[25]

Sundar's research team at the Media Effects Research Laboratory at Pennsylvania State University identified four broad affordances in digital media capable of cueing cognitive heuristics pertinent to making credibility assessments: modality (M), agency (A), interactivity (I), and navigability (N).^[26] The modality affordance, which often appears in the multimedia in digital devices, is the most structural (that is, tied to structure rather than to content) and apparent on an interface and accordingly triggers heuristics related to realism, novelty, and coolness, among factors. The agency affordance relates to identification of the source. Depending on who or what is perceived as a source, cognitive heuristics are triggered and in turn affect the information's perceived credibility. The interactivity affordance of digital media provides cues related to interaction, activity, choice, control, and responsiveness. Finally, the navigability affordance has dual abilities: hyperlinks on a Web site may trigger heuristics given that easily navigable sites have perceived credibility, and words on the hyperlink trigger different heuristics more closely related to the nature of the content. These four affordances are all structural features that help explain the perceived credibility of digital media beyond content characteristics. The affordances are associated with first impressions of surface-level characteristics of Web sites, which are capable of amplifying or diminishing content effects on credibility. The core idea of Sundar's model is that, while cues and heuristics do not guarantee success, they likely appeal to many individuals striving to cope with the deluge of information.

Hilligoss and Rieh's credibility framework also considers heuristics as an important component of credibility assessment.^[27] The results of an empirical study about people's credibility assessment in a variety of everyday life information-seeking contexts identified three distinct levels of credibility judgments: construct, heuristics, and interaction. The construct level involves defining the notion of credibility that influences people's judgments. The heuristics level pertains to general rules of thumb for credibility assessment, applicable to a variety of general information seeking situations. The interaction level refers to credibility judgments in which particular sources or

content cues are characterized. These three levels of credibility assessment are interlinked; for instance, people's constructions of credibility influence the kind of heuristics used in selecting a Web site in which people begin a search. Credibility heuristics can influence the ways in which people pay attention to certain characteristics of information and sources. As people gain more experience with a certain source of information, credibility heuristics can be changed or extended. Should a heuristic prove consistent over time, then it becomes a construct of credibility in people's minds. Their model additionally demonstrates that context is a factor importantly influencing all three levels of credibility assessment. The context is the social, relational, and dynamic frames surrounding people's information-seeking processes, creating boundaries around the information-seeking activity or the credibility judgment itself. The context of credibility judgments can either guide the selection of resources or limit judgment applicability.

CONCLUSION

This entry intends to raise awareness about notions of information credibility and cognitive authority in the field of LIS as well as to encourage additional research work in this area. The entry defines two concepts, introduces key terms and dimensions, and discusses major theories and models proposed and tested in LIS and related fields. It also lays out the foundations of credibility and cognitive authority in historical contexts in order to illustrate the importance of understanding and enhancing these concepts as foci of research and practice.

Assessment of credibility and cognitive authority is a ubiquitous human activity, given that people constantly make decisions and selections based on the value of information in a variety of school, work, and everyday life contexts. Further, credibility and cognitive authority assessment can be seen as an ongoing and iterative process rather than a discrete evaluation event. The judgments made in assessment processes are highly dependent upon people's accumulated beliefs, existing knowledge, and prior experiences. While information objects, sources, and media often provide clues and bases for assessment, it is eventually people who make assessment with respect to their information seeking goals and motivations.

Credibility and cognitive authority have long been significant concepts for both researchers and practitioners in LIS and communication fields. Theoretical developments and applications are still emerging and evolving given changing information and communication technology environments. Previous credibility research has looked at people as information consumers while holding rather narrow views of information activities, for example, by focusing on seeking, reading, receiving, and watching. Today, more people are engaging in a broad range of information

activities, such as creating and mediating content while actively utilizing new and diverse information technology tools and applications. Further empirical studies need to be conducted to investigate new kinds of research problems that reflect dynamic and complex information seeking and use contexts. Additional broad and multidisciplinary theoretical frameworks need to be constructed to represent a variety of human information behaviors beyond information seeking and retrieving. Creative and insightful inquiries from researchers and practitioners into credibility and cognitive authority in the LIS field would lead to efficient systems and programs that will eventually help people become more effective information users.

Višnja Zgaga

Museum Documentation Center, Zagreb, Croatia,

Abstract

This entry provides a short historical overview of the oldest writing systems, manuscripts, and books in Croatia. It describes the emergence of the first libraries, archives, and museums from the ninth to the twentieth centuries followed by a description of the present-day situation in the information professions, including legislation regulating the field, the most important libraries, archives and museums, professional associations, professional education, and continuing professional training. The conclusion discusses examples of present-day cooperation between information institutions.

INTRODUCTION

The Republic of Croatia is located in the south-east of Europe. It shares borders with Slovenia to the west, Hungary to the north, and Serbia, Bosnia, and Herzegovina and Montenegro to the east and south-east. The Adriatic Sea forms its southern border with Italy (see Fig. 1). Croatia covers an area of 56,538 km² and has a population of 4,491,543 (July 2008 est.).

According to its geographical position Croatia is a southeastern and Mediterranean country. Its location has had a significant impact on its historical development. From the ninth to the end of the eleventh century it was an independent principedom and kingdom. In 1102 it formed a union with Hungary. Starting in 1527, rulers from the House of Habsburg also became kings of Croatia. As the result of Turkish invasions in the fifteenth century, its geographic holdings were diminished both in the south and in the west. From 1409 until 1797, the coastal area along the Adriatic Sea fell under the administration of the Republic of Venice. Dubrovnik enjoyed a special status, first as an independent commune, and as the Republic of Ragusa from the fifteenth century onward. Despite attempts to unify Croatian lands after the fall of the Republic of Venice in 1797, Northern Croatia still remained in a state union with Hungary, while Dalmatia became a province to the Emperor of Austria, except for the short period between 1806 and 1814, when along with Istria it fell under the French administration, first as part of the Kingdom of Italy and after 1809 as part of the Provinces of Illyria. A stronger movement toward unification arose in the 1830s during the national revival movement. In 1918, Croatian lands were partly unified when Croatia entered the union of the Kingdom of Serbs, Croats, and

Slovenes (as of 1929 the Kingdom of Yugoslavia), and were finally fully unified only after World War II when Istria joined in as part of the Federal People's Republic of Yugoslavia (FPRY). Following the dissolution of Yugoslavia in 1991, Croatia became an independent internationally recognized state in 1992.

LITERACY, BOOKS, AND LIBRARIES

Historical Overview

The political division of Croatian lands determined their affiliation to different cultures. The coastal part of Croatia was under the strong influence of the Mediterranean cultural heritage, while northern Croatia was characterized by central European culture. Croats arrived to their present homeland as illiterate in the seventh century. In the ninth century they converted to Christianity and first wrote in the Latin language and in the Latin script. This language and script appears both on stone monuments and in the correspondence between princes, kings, and bishops with popes and other rulers of that time.^[1] From the eleventh century in the southwestern regions of Croatia two other indigenous scripts were used along with Latin: the Glagolitic alphabet and the Croatian Cyrillic alphabet (bosančica). These were used to record texts in the Old Slavic and the national Croatian languages. The oldest preserved Glagolitic texts written on stone monuments date from the eleventh century. One of the most famous is the Valun Tablet named after the place on the island of Cres where it was found, containing bilingual inscriptions in Croatian and Latin. The Croatian text is written in Glagolitic script and the Latin in Carolingian script. The

Baška Tablet dating from 1100 also carries great significance for Croatian cultural history. It is a stone monument inscribed in the Glagolitic script which was discovered in Baška on the island of Krk and in it, a Croatian name is mentioned for the very first time. From the river Una in the north to Boka Kotorska in the south, the Croatian Cyrillic alphabet was used, a variant of the Cyrillic alphabet originating from tenth century Bulgaria. The parallel use of the Glagolitic and Cyrillic alphabets is evidenced by stone epigraphs dating from the twelfth century and Glagolitic manuscripts in which dates, names of authors and transcribers, prayers and similar addenda which scribes or the owners of the manuscripts entered in the Cyrillic alphabet are found.^[2]

Numerous legal and private documents were written in Glagolitic such as laws, town statutes, minutes of town councils, monastery rules and registers, and liturgical books such as the richly illustrated Missal of Prince Novak from 1368 and the Missal of Hrvoje Vukčić Hrvatinčić dating from the beginning of the fifteenth century. Many handwritten books in the Glagolitic were translations or adaptations of Italian and French works (theological manuals, sermons, etc.). Translated from Czech and adapted to Croatian language was the famous *Lucidarius*, a type of medieval encyclopaedia in which all the knowledge of the time was gathered.^[3]

Croatian incunabula were also printed in Glagolitic. The first Croatian printed book is the Missal from 1483. Since the place of printing is not indicated in the colophon, it is supposed that the Missal was printed in Venice

even though some experts attempted to prove that it was created in a domestic printing house of which no direct information has been preserved. The first known printing house in Croatia was established in Senj at the end of the fifteenth century. It is known that at least seven books were printed there in Glagolitic in the period from 1494 to 1508. The Glagolitic script was used for recording the Croatian language until the sixteenth century when the Latin script prevailed, yet in some parts of the country Glagolitic remained in the liturgy until the beginning of the twentieth century.

Literacy, education, book production, and the establishment of libraries were closely connected to monasteries with scriptoria and libraries founded by members of individual church orders from the ninth century onward. Benedictine monks came to Croatia at the invitation of the Prince Trpimir. Their monasteries were the most important cultural centers from the ninth to the thirteenth centuries. Beautifully illustrated medieval manuscripts were created in Benedictine scriptoria, such as the *Evangelium Vekenegae* dating to approximately 1075 (today kept in the Bodleian Library in Oxford) and the *Evangelium Traguriense* from the first half of the thirteenth century (today kept in the treasury of the Trogir Cathedral). Monastery library collections were modest—at the end of the eleventh century they had between 10 and 50 codices. These codices were purchased or acquired as donations from distinguished and wealthy individuals.^[4]

In the thirteenth century new monastic orders arrived in the country. The first Franciscan monasteries were established in the first half of the thirteenth century in Zagreb, Varaždin, Zadar, Šibenik, and Dubrovnik. In the thirteenth and fourteenth centuries Dominican monasteries became important centers of culture. Books and schools were especially important to the Dominicans as a means of fighting against heresy and educating young members of their order. Schools were organized in several Dominican monasteries, and in 1553 in Zadar the Dominicans founded “general studies.” Laymen and members of the order alike were awarded the baccalaureate after completion of the program.

In addition to monastery libraries, diocese libraries also existed in the Middle Ages. The diocese library in Split is considered to be the oldest library in Croatia. In the Middle Ages there was also a scriptorium along with the library. Some of the manuscripts from the oldest period of the library have been preserved to this day in the treasury of the Split Cathedral of which the most famous is the Greek–Latin *Evangelium* known under the name *Evangelium Spalatense*. Historically it was believed that this manuscript originated in the seventh or eighth century, probably from the scriptorium of the diocese, but recent paleographic analysis confirms that it dates from the fifth or sixth century.^[5] The inventories of the Zagreb Diocese Metropolitan Library founded at the end of the eleventh century have been preserved through to the

present, and confirm that the library was well managed. The oldest inventory dates from 1394 and contained several codices from the eleventh century. In the preserved inventories of a later date, books were organized according to a systematic order. Care of the library was usually entrusted to a member of the monastery or chapter community. The Episcopal provision from 1348 established that funds gathered from monetary fines collected in disputes between priests were to be used for renewing library materials.^[6]

The private libraries of writers and scholars of the fifteenth and sixteenth centuries were largely created in Split, Dubrovnik, Zadar, and Hvar—the literary centers of the time. The manuscript catalog of the library of the humanist and poet Marko Marulić (1450–1524), which he himself assembled, has been preserved. The catalog contains 148 volumes of religious works, works of humanists and classical writers.^[7]

In the seventeenth century Jesuits arrived in Croatia and founded ecclesiastical schools (gymnasias) in larger towns: Dubrovnik, Rijeka, Varaždin, Požega, and Zagreb. According to the rules of the order each school had to also have a library. From the library of the Zagreb Jesuit Collegium, founded in 1607, the future Library of the University of Zagreb would develop, known today as the National and University Library. Besides religious orders, noblemen and scholars also possessed libraries. After the execution of the Croatian poet and nobleman Nikola Šubić Zrinski (1620–1664), his library, containing works of classical and contemporary authors, was taken to Austria, but was repurchased in 1892 for the University Library in Zagreb. The systematic catalog of that library dating from 1662 has been preserved.^[8] Partially preserved is the library of the poet, scholar, and librarian of the seminary library in Split, Jerolim Kavanjin (1643–1714).^[9] One of the richest and most valuable private libraries is the library of the Garanjin-Fanfogna family in Trogir, founded at the end of the eighteenth century, which besides manuscripts and books also contains family and other archival records some of which date from as far back as the twelfth century. The first manuscript catalog of the library was composed in 1796.^[10]

At the end of the eighteenth and beginning of the nineteenth century, so-called reading rooms appeared in various towns. These were establishments primarily intended not only for entertainment, dances, and social gatherings, but also reading. Often they were called casinos. So from 1775 in Šibenik there was the Società del Casino, and from 1806 a casino in Rijeka. The first reading room which actually contained the word “reading” in its name was the Gabinetto di lettura, or Druxba od scenja, founded in Zadar in 1807.^[11] Those reading rooms, as well as numerous others newly established in various towns and villages during the period of the National Revival (1835–1849), were called Illyrian. After the ban of the name Illyrian in 1843, they were called public

reading rooms, and were focal points for the spread of ideas of revival. The National Revival strived toward the unification of South Slavs and thought to accomplish that goal by developing a common popular language as a strong tool for raising national awareness. The leader of the movement was Ljudevit Gaj (1809–1872), the reformer of the Croatian orthography (1830), and publisher of *Novine Hrvatske* (Croatian Newspapers) (1835). Public reading rooms appeared to be political organizations participating in the fight for language, national identity, and freedom. Yet the majority of them also had a library which, at least partly, performed some of the present-day library functions. Public reading rooms operated until 1849 when their work was banned.^[12]

Twentieth Century Library Development

Public libraries in today’s sense of the word were established only at the beginning of the twentieth century, when the idea of the need for popular education appeared. Students of the Zagreb University played an important role in transmitting that idea and encouraged the opening of libraries. In 1903, as part of the Croatian Writers Society, the main administration for the establishment of public libraries was founded. In 1906 the Croatian Society for Popular Education in Zagreb, founded for the purpose of performing tasks of establishing, supporting, and monitoring public libraries, joined in those efforts. Because there was still no special legislation which would ensure the continuous financing of libraries, and thus enable them to operate unhindered, libraries were established through donations gathered from individuals. Consequently, they often occupied modest spaces, in community houses, parish houses, town halls, schools, houses or even inns, without anyone looking after them on a regular basis. For that reason they were often short-term efforts and quickly disappeared.^[13]

The situation was similar in libraries in the Kingdom of Yugoslavia. In 1937 Josip Badalić (1888–1985), the librarian of the University Library in Zagreb, wrote the following:

In the field of our public education, public librarianship [in Yugoslavia] seems to have the role of Cinderella. This is entirely true not only in the case of public librarianship, but unfortunately also in the case of state librarianship and all the way to the highest positioned university librarianship. The main reason for this is the inexistence of legislation in the field of our national librarianship. . .^[14]

Despite efforts to promote public library development, the first Library Act would not be passed until 1960.

In World War II many libraries were destroyed. Especially devastating was the loss of the library of the Gymnasium in Zadar, destroyed by bombarding in 1943, because that library used to receive legal deposits from

Dalmatia. Many libraries were also destroyed in the 1991–1995 war. Data confirms that around 200 libraries of all types, including those containing valuable heritage material, were damaged or destroyed.^[15]

Legislation

The current Library Act was adopted in 1997 and amended in 2000. The Act established within the Ministry of Culture an expert advisory body known as the Croatian Library Council. The council is charged with issuing recommendations on all important matters in the field of librarianship. The Library Act also regulates the establishment and maintenance of libraries, the organization and functioning of the library system, the delivery of legal deposits, and the conservation of book heritage.

A special chapter of the Library Act regulates the operation of the National and University Library as the center of the Croatian library system. In addition the Act prescribes that each municipality in the country must establish a public library, or contract a library in another municipality, to perform library services for its citizens. The general operation of libraries is financed by local authorities, but the Ministry of Culture assists in acquiring material, and in securing and equipping adequate library facilities. Libraries must meet the standards stipulating minimum requirements for library operation. Besides standards there are also ordinances which provide detailed descriptions of individual methods and procedures which libraries have a duty to perform.

National and University Library

The National and University Library in Zagreb (Fig. 2) is the largest library in the country, and at the same time performs the function of the national library and the central library of the University of Zagreb. This library was established in 1607 as the library of the Jesuit Gymnasium (Collegium), later the Academy. After the dissolution of the Jesuit order in 1776, it became the library of the Academy of Science (the School of Law, Philosophy and Theology). It enriched its collection primarily through donations. One of the most significant was the personal library of Adam Baltazar Krčelić, a clergyman and historian from Zagreb, who in 1777 left in his last will and testament 757 volumes of books and 50 manuscripts, under the conditions that they be open to the public, which was realized only in 1818. When the University of Zagreb was founded in 1874, it became the University Library.

In the beginning of the nineteenth century, the university library had already begun to perform the function of the national library. In 1837 it acquired the right to legal deposits from northern Croatia. In 1856 it received a permanent donation for the acquisition of books. First located in the building of the university, it moved to a building specially constructed for that purpose in 1913 which it shared with the State Archives. In 1919 it acquired the right to legal deposits from the whole territory of Yugoslavia. In 1943 it was administratively separated from the University and changed its official name to the Croatian National and University Library. After World War II it

Fig. 2 The National and University Library in Zagreb. Photograph: Damir Fabijanić.

was once again named the University Library, although it also performs the function of a national library. By virtue of a federal regulation in 1947, it became the central library of the Republic of Croatia, and after 1945 it again received legal deposits from the whole territory of Yugoslavia. Pursuant to the Library Act from 1960, it changed its name to the National and University Library and began performing the task of coordinating the acquisition of foreign literature for libraries in the country, providing expert assistance to other libraries and creating union catalogs.

In 1995 the library moved in a new building covering an area of 45,000 m². Besides its general collection containing 2.5 million volumes, it also has special collections: a collection of manuscripts and old books, a collection of prints (founded in 1919), a collection of geographical maps and atlases (founded in 1945), and a collection of music and audio materials (founded in 1943). It has 1100 seats for reading and approximately 18,000 users benefit from its services each year. It receives legal deposits, develops and organizes the national collection, develops the national current and retrospective bibliography, and cares for the protection of book heritage. In cooperation with the University Computing Centre SRCE, it harvests national digital publications which it deposits in the Digital Archives of Croatian Web Publications. It also includes the Librarianship Institute whose task is to develop the Croatian library system and librarianship in general. In the year 2001, it initiated a project under the name Digitised Heritage. So far 555 items of various formats (books, music sheets, drawings, graphics, and maps) have been digitized and may be accessed via the Web site of the Library (<http://www.nsk.hr>).

Academic, Research, and Special Libraries

Until the 1970s the University of Zagreb was the only university in Croatia. Today, with its 50,000 students, it is the largest. It was only in 1973 that the University in Rijeka was founded, followed in 1974 by the University in Split and in 1975 the University in Osijek. The newest universities were established in Zadar (2002), Dubrovnik (2003), and Pula (2006).

The universities were for the most part decentralized and consisted of several faculties and schools of higher education in different locations. These circumstances contributed to the emergence of numerous faculty, departmental, seminary, and other libraries at certain faculties; some of them having a very long tradition. The library of the Zagreb Faculty of Law was established back in 1906, the library at the Faculty of Engineering in 1926, at the Faculty of Economics in 1920, and at the Faculty of Veterinary Medicine in 1922. At the Faculty of Philosophy, the largest constituent part of the University of Zagreb, the oldest library is that of the Slavic seminary founded in 1906. The oldest medical library is the library of the School of Public Health and the Institute of Public Health

in Zagreb, established in 1927. That library served the students and professors of the Medical School as the only expert medical library until the Central Medical Library was established in 1947.

In the second half of the twentieth century academic libraries faced many problems: the lack of funds for acquisition of foreign titles (especially journals), inadequate and sparsely equipped facilities, the absence of union catalogs, lack of or informal cooperation between libraries, and the lack of understanding of the need and importance of libraries on the part of the administration. The collection of the National and University Library was mostly oriented toward humanities and could not meet the needs of the university community. In the 1960s a university professor of chemistry, Božo Težak (1907–1980), used the International Permanent Exhibition of Publications ISIP, an exhibiting institution founded in 1951, and developed the Referral Centre of the University as a center for dissemination of scientific and technical information.

At that time the number of special libraries belonging to companies, factories, industrial centers, and scientific institutes also grew. In the 1970s there was a tendency to transform special libraries into information documentation centers that could provide scientific information to assist in the development of the economy. At the level of the Yugoslavian state the System of Scientific and Technical Information project was initiated with the purpose of enabling libraries to provide relevant information. As part of the project, technical equipping of libraries also began. In the 1980s first the National and University Library was automated and gradually other libraries followed suit.

In 1991 the Ministry of Science and Technology initiated CARNet (Croatian Academic and Research Network), first as a project, and as of 1995, as an institution whose purpose is to assist institutions in the field of science and higher education, in adopting and applying information and communication technologies and disseminating knowledge. Today CARNet gathers 238 university institutions and scientific institutes in 37 Croatian cities. In 1994 the Ministry initiated a project intended for academic libraries, called Scientific Information System, whose purpose was to enable access to information sources to users of academic libraries. As part of that project, academic libraries were equipped with computers and connected to the Internet, and training for librarians was organized.

Public and School Libraries

Between 1945 and 1990 numerous public libraries were opened. In 1950 the first children's library with a reading room was opened as a department of the City Library in Zagreb. There, for the first time, open access to collections was introduced. In 1963 the first record collection in the country was opened in that library. In the 1970s the first network of public libraries was established in Zagreb.

Only a few new purpose built facilities were constructed for libraries, for example the City Library in Karlovac got its own building in 1976. It was only after the 1990s that a more significant number of existing buildings and facilities were adapted for city libraries such as the city libraries in Zadar (1999), Šibenik (2005), and Virovitica (2007). Today there are 256 libraries operating.^[16] The majority of public libraries are connected to the Internet and have their own Web pages.

Primary and secondary schools are obligated to establish libraries by law. The adoption of the Library Act in 1997, requiring school librarians to acquire professional qualifications, constituted a significant step toward professionalizing librarianship. There are 1347 libraries of primary and secondary schools in Croatia which are members of CARNet and have Internet access (<http://www.carnet.hr>).

Church Libraries

Monasteries, parishes, and churches possess very valuable collections of heritage material, of which very little is known because many of them are not organized. Consequently, they are not available to the public. The Regulation of the Croatian Conference of Bishops on church libraries from 2000 prescribes that older and more valuable books are to be deposited in the central diocese library or religious province library, which should facilitate the cataloging of heritage material and its final inclusion in the national registry of cultural heritage.

Professional Associations

The Croatian Library Association was founded in 1940 by a small group of librarians from the University Library in Zagreb. Today the association is organized as an umbrella organization of 16 regional library associations with a total of 1400 members. The goals of the Association are described in the Statute adopted in 2002 and include publication of professional literature, organization of conferences and other forms of continuing professional training, proposal of relevant legislation, representation of interests of library service users, promotion of literacy, and care for cultural and book heritage (<http://www.hkdrustvo.hr/hr/statut/>).

The Association is the most important publisher of library science literature in the country. Between 1966, when it published its first title, and 2006, the Association published 95 titles. It is also the publisher of the oldest professional journal *Vjesnik bibliotekara Hrvatske* (1950–). As of 1999, it organizes Days of Special Libraries, an annual meeting of librarians of special and academic libraries. Beginning in 2001 it has organized the annual Round Table on Free Access to Information; these sessions are primarily intended for public librarians. Together with 17 NGOs, the Association participated in

the drafting of the Act on the Right to Information Access, which was adopted in 2003. The association has awarded the Kukuljević Charter, the highest professional acknowledgment, since 1968 and the Eva Verona Award for the best young librarian since 1998.

Library and Information Science Education

Until the 1960s there was no formal schooling available for librarians and professional knowledge was acquired by passing a librarianship examination. Regulations issued in 1928 required that librarians of the University Library must pass the librarianship examination. In 1931 the same requirements were extended to include all librarians in state libraries.^[17] The acquisition of professional knowledge through taking professional examinations would continue, even after the introduction of university librarianship studies. The examinations were no longer required after the Library Act of 1997.

The first university program for librarians started in 1961 as postgraduate studies in librarianship, documentation, and information sciences under the Faculty of Science. As of 1970 the studies were connected directly to the University of Zagreb. The opening of that study program significantly contributed to professionalizing librarianship and helped create a core group of formally educated librarians for all types of libraries but with an emphasis on university libraries. The program finally closed down at the beginning of the 1990s. In 1977 a graduate program in library studies was opened at the Faculty of Philosophy in Zagreb. At first this was a 2-year supplementary study program, but from 1986 onward it was constituted as a 4-year program in Information Science for librarians, archivists, and museology experts. Beginning in 1998 library science could be studied at the University of Osijek, and as of 2003 also at the University of Zadar. Postgraduate studies in information sciences for archivists, librarians, museology experts, and IT experts were started in 1994 at the Faculty of Philosophy in Zagreb. Following the Bologna educational reform the program was revised in 2005, and is now held as a 3-year doctoral study program.

In 2002 the National and University Library, the Libraries of the City of Zagreb, the Department of Information Sciences of the Faculty of Philosophy in Zagreb, and the Croatian Library Association founded the Centre for Continuing Training of Librarians. Annually it organizes an average of 60 one-day courses for more than 1000 librarians (<http://www.nsk.hr/CSSU/>).

ARCHIVES

Historical Overview

The tradition of keeping documents, both in monasteries' and municipal archives, is most pronounced in the

Fig. 3 The chest of privileges of the Kingdom of Croatia, Dalmatia, and Slavonia (*Privilegia regni*) 1643.

coastal region of Croatia (Dubrovnik, Dalmatia, and Istria). The statutes of coastal communes provide numerous stipulations on keeping documents. The Split Statute, from 1312, obligates the municipality of Split to keep records about documents, indicating their quantity and the year of origin; it also specifies the location where they are to be kept and the criteria for access. In northern Croatia, an old tradition of keeping archival records is evident in the chapters which, as “*loca credibilia*”, played a role equal to public notaries in the coastal region. Even though *Archivum Regni* was mentioned in documents as early as in the sixteenth century, it was not until 1643 that the Croatian Parliament passed a stipulation on making a chest (*Cista—Archivum privilegiorum Regni*) for keeping the most important state documents (Fig. 3).

Besides the Kingdom Archives, every county and every free royal town had their own archives where this material was kept. In the times of the Empress Maria Theresa, a reform of archives management was undertaken, and the archival material was processed and the first lists of material compiled. Nikola Škrlec (1729–1799), a royal protonotary, played an important role in these activities. In the first half of the nineteenth century, in the times of the National Revival, the most important cultural institutions were established including the National Museum (1846) and the State Archives (1849).^[18]

A modern archive service was established after 1945: it establishes practices for the care for current records, the creation of a network of archives and drafting modern legislation on archives. Bernard Stulli (1915–1985), director of the Central State Archives, initiated the making of modern information retrieval tools, started a project on keeping records of material located outside the archive, and supported systematic education of archivists, thus playing a particularly important role in the modernization of archive service.

Legislation

Archive services are regulated by the 1997 Act on Archival Material and Archives and amendments to this Act from the year 2000. The Act covers public and private archival material, and records located in records governmental departments before being forwarded to archives. Public archival material is imprescriptible. The Act stipulates the obligations of the creator and the records owner in regard to the process of appraisal, transfer to archives, and the use of archival material. Since all archival material is a part of cultural heritage, the Act stipulates the obligations of all creators and also regulates the circulation of archival material of private origin. Besides legal acts, subordinate legislation, i.e., ordinances, also regulate particular procedures, e.g., the use of archival material, keeping registers in archives, etc.^[19]

The archive service consists of the network of state archives and the statutory possibility of establishing specialized (university, party, church, etc.), city and municipal archives. It falls under the purview of the Department of Archival Activities, Directorate for the Protection of Cultural Heritage, in the Ministry of Culture. Advisory and professional tasks are performed by the Croatian Archival Council as an advisory body to the Minister of Culture. There are 12,680 archival fonds and collections, kept in 14 state archives and 11 collecting centers. In addition, there are 187 other institutions (libraries, museums, religious communities, institutes) where archival material is kept.^[20]

Croatian State Archives

The *Croatian State Archives* originates from the *Archivum Regni*, which dates from 1643. After 1849 it is known by the name of the Royal Regional Archives, acting as an auxiliary office of the Royal Government of Croatia, Slavonia, and Dalmatia. Then in 1870 the Parliament adopted the Legal Article on the Organisation of the State Archives and the Instruction on the use of documents of the State Archives; these two measures established the status of the archive, regulated the use of documents, and stipulated the concentration of archival collections in one location. In 1923 it separated from the state administration, and in 1945 it officially became the Central State Archives. Following the independence of the Republic of Croatia, it became the *Croatian State Archives* (<http://www.arhiv.hr>).

The Croatian State Archives includes

- The Department for Protection and Processing of the Archival Records.
- The Croatian Film Archives.
- The Department for Information and Communication.
- The Central Laboratory for Photography, Micrography and Reprography.

- The Laboratory for Conservation and Restoration.
- The Deposit of the Archbishopric of Zagreb.

The Croatian State Archives keep archival material that originated from the region of northern Croatia (Banska Croatia or the Kingdom of Croatia, Dalmatia, and Slavonia) in the period prior to 1918, and the material resulting from the work of regional and central state bodies of Croatia, covering the period after 1918. Due to specific historical circumstances, material for some parts of Croatia, which is also of importance for the entire county, is kept in the State Archives in Zadar, the State Archives in Rijeka and the State Archives in Dubrovnik.

The *State Archives in Zadar*, dating to the thirteenth century, holds the records of the Municipality of Zadar. In the course of the nineteenth century this archive collected also material from the municipal archives of Dalmatia. The Zadar Archives also keeps material important for the history of the Republic of Venice and for the history of Dalmatia as an Austrian crown province in the period from 1797 until 1918, as well as the material of the Napoleon Administration in the period from 1806 until 1814.^[21]

The *State Archives in Dubrovnik* (<http://www.dad.hr>) contains material originating from the activities of the Dubrovnik municipality since the thirteenth century, and material of the Republic of Ragusa from the beginning of the fifteenth century to the dissolution of the Republic in 1808. The Archives in Dubrovnik has a wider significance for the historical study of the Balkans and the Mediterranean, from the fourteenth century until the fall of the Republic of Ragusa in 1808.^[22]

The *State Archives in Rijeka* (<http://www.riarhiv.hr>) and *in Pazin* (<http://dapa.hr>) contain material for the wider area of Istria and the Croatian Primorje, starting from the Middle Ages with particular strength in materials from the nineteenth and first decades of the twentieth century.^[23]

Other State Archives in Croatia have been established in Bjelovar, Gospić, Karlovac, Križevci, Štrigova, Osijek, Sisak, Slavonski Brod, Split, Šibenik, Varaždin, Vukovar, and Zagreb with the task of collecting and keeping local archival material.

Digital records are received by the archives only rarely. The Croatian State Archives systematically digitizes material of particular archive holdings and collections. Registers of births, marriages, and deaths are digitized, and so is the Croatian Glagolitic heritage located in Croatia and abroad; the collection of cartography and the Cadastre are currently being digitized as well. In 2007 the National Archival Information System (ARHiNET), a Web-based system for description and management of archives was introduced. Digital archival records, digital images of archives, and finding aids have been made available online (<http://arhinet.arhiv.hr>). The system has also been used by the members of the government and public administration, as well as by other

organizations, for providing records schedules to archival institutions.

National Film Archives

The Croatian National Film Archives (*Hrvatska kinoteka*) was established pursuant to the *Cinematography Act* of 1976, operating within the Croatian State Archives since 1979. The film collection includes preserved films produced by Croatian cinematography in the period from 1904 until 2009, and foreign films distributed in Croatia in the period from 1895 until 2009. In addition to films, the Archives also keeps scripts, film photographs, posters, books and magazines, clippings, and video and audio recordings. The Film Archives has a total of 9296 titles of Croatian and foreign films.^[24]

Specialized Archives

The *Croatian Academy of Sciences and Arts Archives* keeps the Glagolitic and Cyrillic manuscripts, a collection of Oriental manuscripts and the manuscript heritage of writers, playwrights, and musicians, as well as archival fonds and collections significant to the history of theatre.^[25] *Religious communities* have rich archival material in episcopal, chapter and monastery archives. Some church archives are located in the state archives deposit (as for example, the Archives of the Zagreb Arch/Bishopric and the Archives of the Zadar Archbishopric).^[26] *Archives of political parties* for the period prior to the Croatian independence (1991) are kept in state archives. After the period of socialism, political parties establish and maintain their own archives.

Publishing and Professional Associations

Archival periodical *Vjestnik Kraljevskog Zemaljskoga arkiva* has been published since 1898, and since 1953 under the name of *Arhivski vjesnik*. Archival journals are published also in Rijeka, Pazin, Osijek, and Split. The first textbooks on archivistics were published after 1945, while foreign professional literature used in education of archivists has been systematically translated since 1991. Professional education of archivists was introduced in the second half of the twentieth century, when persons employed in the archives were first required to pass professional examination. Archivists could enroll in a postgraduate university program in Zadar (1971–1975), or at the University of Zagreb (1961–1992), where a program for graduate students was also established in 1986.

The Croatian Archivist Association was founded in 1954, with the aim to stimulate and promote education and professional training, organize professional and scientific conferences, issue professional publications, and establish professional standards.^[27]

MUSEUMS

History

Prior to the establishment of the first public museum in 1820, collections were established by patricians, intellectuals, and clergy. These were collections of curiosities, encyclopedic museums, or collections of natural history specimens or man-made objects, armory, paintings, treasury, sculptures, etc.^[28] The Archaeological Museum in Split which was established in 1820 moved the following year to the first purpose built museum in Croatia. In the course of the nineteenth century, the general Central-European movement for preservation and promotion of national cultural heritage national museums had a strong influence in Croatia, and the cities Zadar, Osijek, Dubrovnik, and Zagreb established museums open to the public. The efforts of many learned and other societies led to a series of initiatives aimed at founding regional and municipal museums specializing mainly in history, natural science, and art. By the end of the century, fine arts museums (galleries) and museums of arts and crafts were established, and at the beginning of the twentieth century ethnographic museums were opened.^[29]

Many specialized museums were founded in the first half of the twentieth century; examples include a museum of the history of education and pedagogy, museums and collections of medical and agricultural studies, as well as museums devoted to important persons.^[30]

In the second half of the twentieth century, an effort was made to enlarge the museum network by establishing many regional, local and town museums, enacting new legislation, setting up professional associations, and expanding museums' exhibiting and publishing activities. The growth of specialized museums/permanent exhibitions devoted to the World War II and the Partisan movement was evident. In the 1970s the Museum of Medieval Croatian Culture in Split and the Museum of the Ecclesiastical Art in Zadar were opened as the tangible national investments in culture.

Following the war (1991–1995), the museums and their holdings had to be restored.^[31] Great efforts were made to erect new museum buildings, to reorganize museum management and curatorship, to modernize and improve permanent exhibits, to strengthen international exhibiting program, and to implement IC technology.

Legislation and Organization

Museum activity is governed by the Museum Act (1998) and by several ordinances.^[32] As cultural assets, museum holdings and documentation are covered under those ordinances which address the protection of cultural assets. The ordinances provide guidelines on museum documentation, access to museum collections and records, the

maintenance of the museum register, requirements for joining the museum network, professional and technical standards, and the qualifications required for museum staff. The Museum Network was created on the principle of professional competence and flexibility. As a result, it has established unique standards and norms and supported partnerships between museums and other local regional and national heritage and cultural institutions with the aim of pursuing joint projects. The Network also strengthens intermuseum cooperation by encouraging the exchange of services and activities. It is based on two main criteria: the type of a museum and the level of regional responsibility.^[33]

Information and documentation concerning Croatian museums is collected by the Museum Documentation Centre (MDC) established in 1955. The MDC (<http://www.mdc.hr>) is the central information, documentation, and communication point for the Croatian museum network; it keeps the Register of museums, galleries, and collections. The Register is a record of "musealized heritage" and contains information about all museum institutions in Croatia, regardless of their legal or administrative status. In 2006, according to the Register, there were 219 museums with 1428 collections and 617 documentation holdings,^[34] and about 6 million objects; in addition, about 130 church collections and a large number of private collections throughout the country.

General museums are classified as national or regional, local, and town (municipal). The number of national museums is small, and the predominance of national archaeological museums is evident with one third of all museums are archaeological museums. The best known are the Museum of Croatian Archaeological Monuments and the Archaeological Museum in Split, and archaeological museums in Zadar, Pula, Naron, and Osijek. The state makes efforts to support various types of museums, such as a sports museum, a museum of ecclesiastical art, the Croatian history museum, the Croatian naïve art museum, the Old Village in Kumrovec (the birth-place of Josip Broz Tito). Technical (science) and natural history museums are funded by local authorities such as the City of Zagreb.

The famous fine arts museums are the Strossmayer Gallery of Old Masters (Italian Renaissance and Baroque paintings, along with the works of German, Dutch, Flemish, and French artists), the Mimara Museum encompassing three millennia of arts and crafts from various cultures and civilizations, and the Ivan Meštrović Foundation in Split, Zagreb, and Otavice housed in the Meštrović family houses and studios containing sculptures, drawings, and the sculptor's personal archive. The national gallery of art, known as the Modern Gallery in Zagreb, contains works of nineteenth and twentieth centuries' artists.

New museum buildings in Croatia include the Museum of Contemporary Art, the Museum of Evolution and the

Site of Pre-historic Man "Hušnjakovo", and the Archaeological Museum on the Narona Site. Other buildings and sites have been modernized, such as the Science and Technology Site of Nikola Tesla and the Memorial Site in Jasenovac. The computerization of the Croatian museum network started in 2004.^[35] The locally produced *M++ system* has been used by all museums and up to the beginning of 2009 around 1,000,000 museum objects have been recorded and processed. For the time being they are accessible at the local site, but the network will be implemented in the near future. Today 60% of Croatian museums have their own Web site, and a great number of CD-ROMs promoting their holdings were produced. Museum Web site addresses are available at <http://www.mdc.hr>.

Publishing, Staff, and Professional Association

Museum publishing of catalogs, guides, annual reports, monographs, journals and books, and professional journals is an important way of communicating museum knowledge to a wide range of audiences in Croatia. These include *Muzeologija* (1953–) and *Informatica Museologica* (1970–), and *Vijesti muzealaca i konzervatora* (1952–). The total number of museum professional staff is 907. The structure of museum employees is extremely traditional; there is a great lack of PR and marketing experts, and ICT experts. Museum professional associations are organized at the regional and national levels. The national association is the Croatian Museum Association.

CONCLUSION

Apart from the university education organized as a common study program for all three professions, there are also other examples of professional cooperation. Since 1997 the archival, librarianship, and museology professions organize regular AKM annual seminars (Archives, Libraries, Museums) whose goal is to develop cooperation among professions and exchange expertise.

In 2006 the National Programme for the Digitisation of Archival, Library and Museum Records was developed and adopted. This program provides for the development of a referral center or service for assistance. It also monitors digitization projects and supports the creation of a Web reference portal with information and data on digitization projects in progress.
